Linux Standard Base Core Specification 3.~~0~~1

Linux Standard Base Core Specification 3.~~0~~1

Contents

List of Figures

Foreword

This is version 3.~~0~~1 of the Linux Standard Base Core Specification. This specification is part of a family of specifications under the general title "Linux Standard Base". Developers of applications or implementations interested in using the LSB trademark should see the Free Standards Group Certification Policy for details.

Introduction

The LSB defines a binary interface for application programs that are compiled and packaged for LSB-conforming implementations on many different hardware architectures. Since a binary specification shall include information specific to the computer processor architecture for which it is intended, it is not possible for a single document to specify the interface for all possible LSB-conforming implementations. Therefore, the LSB is a family of specifications, rather than a single one.

This document should be used in conjunction with the documents it references. This document enumerates the system components it includes, but descriptions of those components may be included entirely or partly in this document, partly in other documents, or entirely in other reference documents. For example, the section that describes system service routines includes a list of the system routines supported in this interface, formal declarations of the data structures they use that are visible to applications, and a pointer to the underlying referenced specification for information about the syntax and semantics of each call. Only those routines not described in standards referenced by this document, or extensions to those standards, are described in the detail. Information referenced in this way is as much a part of this document as is the information explicitly included here.

The specification carries a version number of either the form `x.y` or `x.y.z`. This version number carries the following meaning:

- The first number (`x`) is the major version number. All versions with the same major version number should share binary compatibility. Any addition or deletion of a new library results in a new version number. Interfaces marked as `deprecated` may be removed from the specification at a major version change.
- The second number (`y`) is the minor version number. Individual interfaces may be added if all certified implementations already had that (previously undocumented) interface. Interfaces may be marked as `deprecated` at a minor version change. Other minor changes may be permitted at the discretion of the LSB workgroup.
- The third number (`z`), if present, is the editorial level. Only editorial changes should be included in such versions.

Since this specification is a descriptive Application Binary Interface, and not a source level API specification, it is not possible to make a guarantee of 100% backward compatibility between major releases. However, it is the intent that those parts of the binary interface that are visible in the source level API will remain backward compatible from version to version, except where a feature marked as "Deprecated" in one release may be removed from a future release.

Implementors are strongly encouraged to make use of symbol versioning to permit simultaneous support of applications conforming to different releases of this specification.

1

I Introductory Elements

1 Scope

1.1 General

The Linux Standard Base (LSB) defines a system interface for compiled applications and a minimal environment for support of installation scripts. Its purpose is to enable a uniform industry standard environment for high-volume applications conforming to the LSB.

These specifications are composed of two basic parts: A common specification ("LSB-generic" or "generic LSB") describing those parts of the interface that remain constant across all implementations of the LSB, and an architecture-specific ~~specification~~ supplement ("LSB-arch" or "archLSB") describing the parts of the interface that vary by processor architecture. Together, the LSB-generic and the architecture-specific supplement for a single hardware architecture provide a complete interface specification for compiled application programs on systems that share a common hardware architecture.

The LSB-generic document shall be used in conjunction with an architecture-specific supplement. Whenever a section of the LSB-generic specification shall be supplemented by architecture-specific information, the LSB-generic document includes a reference to the architecture supplement. Architecture supplements may also contain additional information that is not referenced in the LSB-generic document.

The LSB contains both a set of Application Program Interfaces (APIs) and Application Binary Interfaces (ABIs). APIs may appear in the source code of portable applications, while the compiled binary of that application may use the larger set of ABIs. A conforming implementation shall provide all of the ABIs listed here. The compilation system may replace (e.g. by macro definition) certain APIs with calls to one or more of the underlying binary interfaces, and may insert calls to binary interfaces as needed.

The LSB is primarily a binary interface definition. Not all of the source level APIs available to applications may be contained in this specification.

1.2 Module Specific Scope

This is the Core module of the Linux Standards Base (LSB). This module provides the fundamental system interfaces, libraries, and runtime environment upon which all conforming applications and libraries depend.

Interfaces described in this module are mandatory except where explicitly listed otherwise. Core interfaces may be supplemented by other modules; all modules are built upon the core.

~~2 Normative References~~

~~The specifications listed below are referenced in whole or in part by the Linux Standard Base. In this specification, where only a particular section of one of these references is identified, then the normative reference is to that section alone, and the rest of the referenced document is informative.~~

2 References

2.1 Normative References

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

> **Note:** Where copies of a document are available on the World Wide Web, a Uniform Resource Locator (URL) is given for informative purposes only. This may point to a more recent copy of the referenced specification, or may be out of date. Reference copies of specifications at the revision level indicated may be found at the Free Standards Group's Reference Specifications (http://refspecs.freestandards.org) site.

3 Requirements

3.1 Relevant Libraries

The libraries listed in Table 3-1 shall be available on a Linux Standard Base system, with the specified runtime names. The libraries listed in Table 3-2 are architecture specific, but shall be available on all LSB conforming systems. This list may be supplemented or amended by the architecture~~-~~ specific ~~specifications~~supplement.

Table 3-1 Standard Library Names

Library	Runtime Name
libdl	libdl.so.2
libcrypt	libcrypt.so.1
libz	libz.so.1
libncurses	libncurses.so.5
libutil	libutil.so.1
libpthread	libpthread.so.0
librt	librt.so.1
libpam	libpam.so.0
libgcc_s	libgcc_s.so.1

Table 3-2 Standard Library Names defined in the Architecture Specific Supplement

Library	Runtime Name
libm	See archLSB
libc	See archLSB
proginterp	See archLSB

These libraries will be in an implementation-defined directory which the dynamic linker shall search by default.

3.2 LSB Implementation Conformance

A conforming implementation is necessarily architecture specific, and must provide the interfaces specified by both the generic LSB Core specification and its relevant architecture specific supplement.

> **Rationale:** An implementation must provide *at least* the interfaces specified in these specifications. It may also provide additional interfaces.

A conforming implementation shall satisfy the following requirements:

- ~~The implementation shall implement fully the architecture described in the hardware manual for the target processor architecture.~~

- A processor architecture represents a family of related processors which may not have identical feature sets. The architecture specific supplement to this specification for a given target processor architecture describes a minimum acceptable processor. The implementation shall provide all features of this processor, whether in hardware or through emulation transparent to the application.
- The implementation shall be capable of executing compiled applications having the format and using the system interfaces described in this document.
- The implementation shall provide libraries containing the interfaces specified by this document, and shall provide a dynamic linking mechanism that allows these interfaces to be attached to applications at runtime. All the interfaces shall behave as specified in this document.
- The map of virtual memory provided by the implementation shall conform to the requirements of this document.
- The implementation's low-level behavior with respect to function call linkage, system traps, signals, and other such activities shall conform to the formats described in this document.
- The implementation shall provide all of the mandatory interfaces in their entirety.
- The implementation may provide one or more of the optional interfaces. Each optional interface that is provided shall be provided in its entirety. The product documentation shall state which optional interfaces are provided.
- The implementation shall provide all files and utilities specified as part of this document in the format defined here and in other referenced documents. All commands and utilities shall behave as required by this document. The implementation shall also provide all mandatory components of an application's runtime environment that are included or referenced in this document.
- The implementation, when provided with standard data formats and values at a named interface, shall provide the behavior defined for those values and data formats at that interface. However, a conforming implementation may consist of components which are separately packaged and/or sold. For example, a vendor of a conforming implementation might sell the hardware, operating system, and windowing system as separately packaged items.
- The implementation may provide additional interfaces with different names. It may also provide additional behavior corresponding to data values outside the standard ranges, for standard named interfaces.

3.3 LSB Application Conformance

A conforming application is necessarily architecture specific, and must conform to both the generic LSB Core specification and its relevant architecture specific supplement.

A conforming application shall satisfy the following requirements:

- Its executable files ~~are~~ shall be either shell scripts or object files in the format defined for the Object File Format system interface.
- Its object files shall participate in dynamic linking as defined in the Program Loading and Linking System interface.
- It ~~employs~~shall employ only the instructions, traps, and other low-level facilities defined in the Low-Level System interface as being for use by applications.

- If it requires any optional interface defined in this document in order to be installed or to execute successfully, the requirement for that optional interface ~~is~~shall be stated in the application's documentation.
- It ~~does~~shall not use any interface or data format that is not required to be provided by a conforming implementation, unless:
  - If such an interface or data format is supplied by another application through direct invocation of that application during execution, that application ~~is~~shall be in turn an LSB conforming application.
  - The use of that interface or data format, as well as its source, ~~is~~shall be identified in the documentation of the application.
- It shall not use any values for a named interface that are reserved for vendor extensions.

A strictly conforming application ~~does~~shall not require or use any interface, facility, or implementation-defined extension that is not defined in this document in order to be installed or to execute successfully.

4 Definitions

For the purposes of this document, the following definitions, as specified in the *ISO/IEC Directives, Part 2, 2001, 4th Edition*, apply:

can

be able to; there is a possibility of; it is possible to

cannot

be unable to; there is no possibilty of; it is not possible to

may

is permitted; is allowed; is permissible

need not

it is not required that; no...is required

shall

is to; is required to; it is required that; has to; only...is permitted; it is necessary

shall not

is not allowed [permitted] [acceptable] [permissible]; is required to be not; is required that...be not; is not to be

should

it is recommended that; ought to

should not

it is not recommended that; ought not to

5 Terminology

For the purposes of this document, the following terms apply:

archLSB

The architectural part of the LSB Specification which describes the specific parts of the interface that are platform specific. The archLSB is complementary to the gLSB.

Binary Standard

The total set of interfaces that are available to be used in the compiled binary code of a conforming application.

gLSB

The common part of the LSB Specification that describes those parts of the interface that remain constant across all hardware implementations of the LSB.

implementation-defined

Describes a value or behavior that is not defined by this document but is selected by an implementor. The value or behavior may vary among implementations that conform to this document. An application should not rely on the existence of the value or behavior. An application that relies on such a value or behavior cannot be assured to be portable across conforming implementations. The implementor shall document such a value or behavior so that it can be used correctly by an application.

Shell Script

A file that is read by an interpreter (e.g., awk). The first line of the shell script includes a reference to its interpreter binary.

Source Standard

The set of interfaces that are available to be used in the source code of a conforming application.

undefined

Describes the nature of a value or behavior not defined by this document which results from use of an invalid program construct or invalid data input. The value or behavior may vary among implementations that conform to this document. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

unspecified

Describes the nature of a value or behavior not specified by this document which results from use of a valid program construct or valid data input. The value or behavior may vary among implementations that conform to this document. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

Other terms and definitions used in this document shall have the same meaning as defined in Chapter 3 of the Base Definitions volume of ISO POSIX (2003).

6 Documentation Conventions

Throughout this document, the following typographic conventions are used:

`function()`

the name of a function

command

the name of a command or utility

`CONSTANT`

a constant value

`parameter`

a parameter

`variable`

a variable

Throughout this specification, several tables of interfaces are presented. Each entry in these tables has the following format:

name

the name of the interface

(symver)

An optional symbol version identifier, if required.

[*`refno`*]

A reference number indexing the table of referenced specifications that follows this table.

For example,

forkpty(GLIBC_2.0) [~~1~~]SUSv3]

refers to the interface named `forkpty()` with symbol version `GLIBC_2.0` that is defined in the ~~first of~~`SUSv3` reference.

Note: Symbol versions are defined in the ~~listed references below the table~~architecture specific supplements only.

7 Relationship To ISO/IEC 9945 POSIX

This specification includes many interfaces described in ISO POSIX (2003). Unless otherwise specified, such interfaces should behave exactly as described in that specification. Any conflict between the requirements described here and the ISO POSIX (2003) standard is unintentional, except as explicitly noted otherwise.

> **Note:** In addition to the differences noted inline in this specification, PDTR 24715 has extracted the differences between this specification and ISO POSIX (2003) into a single place. It is the long term plan of the ~~LSB~~ Free Standards Group to converge the LSB Core Specification with ISO/IEC 9945 POSIX.

The LSB Specification Authority is responsible for deciding the meaning of conformance to normative referenced standards in the LSB context. Problem Reports regarding underlying or referenced standards in any other context will be referred to the relevant maintenance body for that standard.

8 Relationship To Other Free Standards Group Specifications

The LSB is the base for several other specification projects under the umbrella of the Free Standards Group (FSG). This specification is the foundation, and other specifications build on the interfaces defined here. However, beyond those specifications listed as Normative References, this specification has no dependencies on other FSG projects.

II Executable And Linking Format (ELF)

9 Introduction

Executable and Linking Format (ELF) defines the object format for compiled applications. This specification supplements the information found in System V ABI Update and is intended to document additions made since the publication of that document.

10 Low Level System Information

10.1 Operating System Interface

LSB-conforming applications shall assume that stack, heap and other allocated memory regions will be non-executable. The application must take steps to make them executable if needed.

10.2 Machine Interface

10.2.1 Data Representation

LSB-conforming applications shall use the data representation as defined in the Arcitecture specific ELF documents.

10.2.1.1 Fundamental Types

In addition to the fundamental types specified in the ~~Architecture~~architecture specific ~~ELF documents~~supplement, a 1 byte data type is defined here.

Table 10-1 Scalar Types

Type	C	C++	`sizeof`	Alignment (bytes)	Architecture Representation
Integral	_Bool	bool	1	1	byte

11 Object Format

11.1 Object Files

LSB-conforming implementations shall support the object file Executable and Linking Format (ELF), which is defined by the following documents:

- System V ABI
- System V ABI Update
- this ~~document~~specification
- an architecture~~-~~ specific ~~LSB~~supplement to this specification

Conforming implementations may also support other unspecified object file formats.

11.2 Sections

11.2.1 Introduction

As described in System V ABI, an ELF object file contains a number of *sections*.

11.2.2 Sections Types

The section header table is an array of `Elf32_Shdr` or `Elf64_Shdr` structures as described in System V ABI. The *`sh_type`* member shall be either a value from Table 11-1, drawn from the System V ABI, or one of the additional values specified in Table 11-2.

A section header's *`sh_type`* member specifies the sections's semantics.

11.2.2.1 ELF Section Types

The following section types are defined in the System V ABI and the System V ABI Update.

Table 11-1 ELF Section Types

Name	Value	Description
SHT_DYNAMIC	0x6	The section holds information for dynamic linking. Currently, an object file shall have only one dynamic section, but this restriction may be relaxed in the future. See `Dynamic Section' in Chapter 5 for details.
SHT_DYNSYM	0xb	This section holds a minimal set of symbols adequate for dynamic linking. See also SHT_SYMTAB. Currently, an object file may have either a section of

Name	Value	Description
		SHT_SYMTAB type or a section of SHT_DYNSYM type, but not both. This restriction may be relaxed in the future.
SHT_FINI_ARRAY	0xf	This section contains an array of pointers to termination functions, as described in `Initialization and Termination Functions' in Chapter 5. Each pointer in the array is taken as a parameterless procedure with a void return.
SHT_HASH	0x5	The section holds a symbol hash table. Currently, an object file shall have only one hash table, but this restriction may be relaxed in the future. See `Hash Table' in the Chapter 5 for details.
SHT_INIT_ARRAY	0xe	This section contains an array of pointers to initialization functions, as described in `Initialization and Termination Functions' in Chapter 5. Each pointer in the array is taken as a parameterless procedure with a void return.
SHT_NOBITS	0x8	A section of this type occupies no space in the file but otherwise resembles SHT_PROGBITS. Although this section contains no bytes, the sh_offset member contains the conceptual file offset.
SHT_NOTE	0x7	The section holds information that marks the file in some way. See `Note Section' in Chapter 5 for details.

Name	Value	Description
SHT_NULL	0x0	This value marks the section header as inactive; it does not have an associated section. Other members of the section header have undefined values.
SHT_PREINIT_ARRAY	0x10	This section contains an array of pointers to functions that are invoked before all other initialization functions, as described in `Initialization and Termination Functions' in Chapter 5. Each pointer in the array is taken as a parameterless proceure with a void return.
SHT_PROGBITS	0x1	The section holds information defined by the program, whose format and meaning are determined solely by the program.
SHT_REL	0x9	The section holds relocation entries without explicit addends, such as type Elf32_Rel for the 32-bit class of object files or type Elf64_Rel for the 64-bit class of object files. An object file may have multiple relocation sections. See "Relocation"
SHT_RELA	0x4	The section holds relocation entries with explicit addends, such as type Elf32_Rela for the 32-bit class of object files or type Elf64_Rela for the 64-bit class of object files. An object file may have multiple relocation sections. `Relocation' b
SHT_STRTAB	0x3	The section holds a string table. An object file may have multiple string table

Name	Value	Description
		sections. See `String Table' below for details.
SHT_SYMTAB	0x2	This section holds a symbol table. Currently, an object file may have either a section of SHT_SYMTAB type or a section of SHT_DYNSYM type, but not both. This restriction may be relaxed in the future. Typically, SHT_SYMTAB provides symbols for link editing, though it may also be used for dynamic linking. As a complete symbol table, it may contain many symbols unnecessary for dynamic linking.

11.2.2.2 Additional Section Types

The following additional section types are defined here.

Table 11-2 Additional Section Types

Name	Value	Description
SHT_GNU_verdef	0x6ffffffd	This section contains the symbol versions that are provided.
SHT_GNU_verneed	0x6ffffffe	This section contains the symbol versions that are required.
SHT_GNU_versym	0x6fffffff	This section contains the Symbol Version Table.

11.3 Special Sections

11.3.1 Special Sections

Various sections hold program and control information. Sections in the lists below are used by the system and have the indicated types and attributes.

11.3.1.1 ELF Special Sections

The following sections are defined in the System V ABI and the System V ABI Update.

29 **Table 11-3 ELF Special Sections**

Name	Type	Attributes
.bss	SHT_NOBITS	SHF_ALLOC+SHF_WRITE
.comment	SHT_PROGBITS	0
.data	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE
.data1	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE
.debug	SHT_PROGBITS	0
.dynamic	SHT_DYNAMIC	SHF_ALLOC+SHF_WRITE
.dynstr	SHT_STRTAB	SHF_ALLOC

.tdata	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE+SHF_TLS

Name	Type	Attributes
.text	SHT_PROGBITS	SHF_ALLOC+SHF_EXECINSTR

.bss

This section holds data that contributes to the program's memory image. The program may treat this data as uninitialized. However, the system shall initialize this data with zeroes when the program begins to run. The section occupies no file space, as indicated by the section type, SHT_NOBITS

.comment

This section holds version control information.

.data

This section holds initialized data that contribute to the program's memory image.

.data1

This section holds initialized data that contribute to the program's memory image.

.debug

This section holds information for symbolic debugging. The contents are unspecified. All section names with the prefix .debug hold information for symbolic debugging. The contents of these sections are unspecified.

.dynamic

This section holds dynamic linking information. The section's attributes will include the SHF_ALLOC bit. Whether the SHF_WRITE bit is set is processor specific. See Chapter 5 for more information.

.dynstr

This section holds strings needed for dynamic linking, most commonly the strings that represent the names associated with symbol table entries. See Chapter 5 for more information.

.dynsym

This section holds the dynamic linking symbol table, as described in `Symbol Table'. See Chapter 5 for more information.

.fini

This section holds executable instructions that contribute to the process termination code. That is, when a program exits normally, the system arranges to execute the code in this section.

.fini_array

This section holds an array of function pointers that contributes to a single termination array for the executable or shared object containing the section.

.hash

This section holds a symbol hash table. See `Hash Table' in Chapter 5 for more information.

.init

This section holds executable instructions that contribute to the process initialization code. When a program starts to run, the system arranges to execute the code in this section before calling the main program entry point (called main for C programs)

.init_array

This section holds an array of function pointers that contributes to a single initialization array for the executable or shared object containing the section.

.interp

This section holds the path name of a program interpreter. If the file has a loadable segment that includes relocation, the sections' attributes will include the SHF_ALLOC bit; otherwise, that bit will be off. See Chapter 5 for more information.

.line

This section holds line number information for symbolic debugging, which describes the correspondence between the source program and the machine code. The contents are unspecified.

.note

This section holds information in the format that `Note Section' in Chapter 5 describes of the System V Application Binary Interface, Edition 4.1.

.preinit_array

This section holds an array of function pointers that contributes to a single pre-initialization array for the executable or shared object containing the section.

.rodata

This section holds read-only data that typically contribute to a non-writable segment in the process image. See `Program Header' in Chapter 5 for more information.

.rodata1

This section hold sread-only data that typically contribute to a non-writable segment in the process image. See `Program Header' in Chapter 5 for more information.

.shstrtab

This section holds section names.

.strtab

This section holds strings, most commonly the strings that represent the names associated with symbol table entries. If the file has a loadable segment that

106 includes the symbol string table, the section's attributes will include the
107 SHF_ALLOC bit; otherwi

108 .symtab

109 This section holds a symbol table, as `Symbol Table'. in this chapter describes. If
110 the file has a loadable segment that includes the symbol table, the section's
111 attributes will include the SHF_ALLOC bit; otherwise, that bit will be off.

112 .tbss

113 This section holds uninitialized thread-local data that contribute to the
114 program's memory image. By definition, the system initializes the data with
115 zeros when the data is instantiated for each new execution flow. The section
116 occupies no file space, as indicated by the section type, SHT_NOBITS.
117 Implementations need not support thread-local storage.

118 .tdata

119 This section holds initialized thread-local data that contributes to the program's
120 memory image. A copy of its contents is instantiated by the system for each new
121 execution flow. Implementations need not support thread-local storage.

122 .text

123 This section holds the `text,' or executable instructions, of a program.

124 #### 11.3.1.2 Additional Special Sections

125 Object files in an LSB conforming application may also contain one or more of the
126 additional special sections described below.

127 **Table 11-4 Additional Special Sections**

Name	Type	Attributes
.ctors	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE
.data.rel.ro	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE
.dtors	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE
.eh_frame	SHT_PROGBITS	SHF_ALLOC
.eh_frame_hdr	SHT_PROGBITS	SHF_ALLOC
.gcc_except_table	SHT_PROGBITS	SHF_ALLOC
.gnu.version	SHT_GNU_versym	SHF_ALLOC
.gnu.version_d	SHT_GNU_verdef	SHF_ALLOC
.gnu.version_r	SHT_GNU_verneed	SHF_ALLOC
.got.plt	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE
.jcr	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE

Name	Type	Attributes
.note.ABI-tag	SHT_NOTE	SHF_ALLOC
.stab	SHT_PROGBITS	0
.stabstr	SHT_STRTAB	0

.ctors

This section contains a list of global constructor function pointers.

.data.rel.ro

This section holds initialized data that contribute to the program's memory image. This section may be made read-only after relocations have been applied.

.dtors

This section contains a list of global destructor function pointers.

.eh_frame

This section contains information necessary for frame unwinding during exception handling. See Section 11.6.1.

.eh_frame_hdr

This section contains a pointer to the .eh_frame section which is accessible to the runtime support code of a C++ application. This section may also contain a binary search table which may be used by the runtime support code to more efficiently access records in the .eh_frame section. See Section 11.6.2.

.gcc_except_table

This section holds ~~LSDA data~~Language Specific Data.

.gnu.version

This section contains the Symbol Version Table. See Section 11.7.2.

.gnu.version_d

This section contains the Version Definitions. See Section 11.7.3.

.gnu.version_r

This section contains the Version ~~Requirments~~Requirements. See Section 11.7.4.

.got.plt

This section holds the read-only portion of the GLobal Offset Table. This section may be made read-only after relocations have been applied.

.jcr

This section contains information necessary for registering compiled Java classes. The contents are compiler-specific and used by compiler initialization functions.

.note.ABI-tag

Specify ABI details. See Section 11.8.

.stab

This section contains debugging information. The contents are not specified as part of the LSB.

.stabstr

This section contains strings associated with the debugging infomation contained in the .stab section.

11.4 Symbol Mapping

11.4.1 Introduction

Symbols in a source program are translated by the compilation system into symbols that exist in the object file.

11.4.1.1 C Language

External C symbols shall be unchanged in an object file's symbol table.

11.5 DWARF Extensions

The LSB does not specify debugging information, however, some additional sections contain information which is encoded using the the encoding as specified by DWARF Debugging Information Format, Revision 2.0.0 with extensions defined here.

Note: The extensions specified here also exist in DWARF Debugging Information Format, Revision 3.0.0 (Draft). It is expected that future versions of the LSB will reference the final version of that document, and that the definitions here will be taken from that document instead of being specified here.

11.5.1 DWARF Exception Header Encoding

The DWARF Exception Header Encoding is used to describe the type of data used in the `.eh_frame` and `.eh_frame_hdr` section. The upper 4 bits indicate how the value is to be applied. The lower 4 bits indicate the format of the data.

Table 11-5 DWARF Exception Header value format

Name	Value	Meaning
DW_EH_PE_absptr	0x00	The Value is a literal pointer whose size is determined by the architecture.
DW_EH_PE_uleb128	0x01	Unsigned value is encoded using the Little Endian Base 128 (LEB128) as defined by DWARF Debugging Information Format, Revision 2.0.0.
DW_EH_PE_udata2	0x02	A 2 bytes unsigned value.

Name	Value	Meaning
DW_EH_PE_udata4	0x03	A 4 bytes unsigned value.
DW_EH_PE_udata8	0x04	An 8 bytes unsigned value.
DW_EH_PE_sleb128	0x09	Signed value is encoded using the Little Endian Base 128 (LEB128) as defined by DWARF Debugging Information Format, Revision 2.0.0.
DW_EH_PE_sdata2	0x0A	A 2 bytes signed value.
DW_EH_PE_sdata4	0x0B	A 4 bytes signed value.
DW_EH_PE_sdata8	0x0C	An 8 bytes signed value.

Table 11-6 DWARF Exception Header application

Name	Value	Meaning
DW_EH_PE_pcrel	0x10	Value is relative to the current program counter.
DW_EH_PE_textrel	0x20	Value is relative to the beginning of the .text section.
DW_EH_PE_datarel	0x30	Value is relative to the beginning of the .got or .eh_frame_hdr section.
DW_EH_PE_funcrel	0x40	Value is relative to the beginning of the function.
DW_EH_PE_aligned	0x50	Value is aligned to an address unit sized boundary.

One special encoding, 0xff (DW_EH_PE_omit), shall be used to indicate that no value ispresent.

11.5.2 DWARF CFI Extensions

In addition to the Call Frame Instructions defined in section 6.4.2 of DWARF Debugging Information Format, Revision 2.0.0, the following additional Call Frame Instructions may also be used.

Table 11-7 Additional DWARF Call Frame Instructions

Name	Value	Meaning
DW_CFA_expression	0x10	The DW_CFA_expression

Name	Value	Meaning
		instruction takes two operands: an unsigned LEB128 value representing a register number, and a DW_FORM_block value representing a DWARF expression. The required action is to establish the DWARF expression as the means by which the address in which the given register contents are found may be computed. The value of the CFA is pushed on the DWARF evaluation stack prior to execution of the DWARF expression. The DW_OP_call2, DW_OP_call4, DW_OP_call_ref and DW_OP_push_object_address DWARF operators (see Section 2.4.1 of DWARF Debugging Information Format, Revision 2.0.0) cannot be used in such a DWARF expression.
DW_CFA_offset_extended_sf	0x11	The DW_CFA_offset_extended_sf instruction takes two operands: an unsigned LEB128 value representing a register number and a signed LEB128 factored offset. This instruction is identical to DW_CFA_offset_extended except that the second operand is signed.
DW_CFA_def_cfa_sf	0x12	The DW_CFA_def_cfa_sf instruction takes two operands: an unsigned LEB128 value representing a register number and a signed LEB128 factored offset.

Name	Value	Meaning
		This instruction is identical to DW_CFA_def_cfa except that the second operand is signed and factored.
DW_CFA_def_cfa_offset_sf	0x13	The DW_CFA_def_cfa_offset_sf instruction takes a signed LEB128 operand representing a factored offset. This instruction is identical to DW_CFA_def_cfa_offset except that the operand is signed and factored.
DW_CFA_GNU_args_size	0x2e	The DW_CFA_GNU_args_size instruction takes an unsigned LEB128 operand representing an argument size. This instruction specifies the total of the size of the arguments which have been pushed onto the stack.
DW_CFA_GNU_negative_offset_extended	0x2f	The DW_CFA_def_cfa_sf instruction takes two operands: an unsigned LEB128 value representing a register number and an unsigned LEB128 which represents the magnitude of the offset. This instruction is identical to DW_CFA_offset_extended_sf except that the operand is subtracted to produce the offset. This instructions is obsoleted by DW_CFA_offset_extended_sf.

11.6 Exception Frames

When using languages that support exceptions, such as C++, additional information must be provided to the runtime environment that describes the call frames that

must be unwound during the processing of an exception. This information is contained in the special sections `.eh_frame` and `.eh_framehdr`.

> **Note:** The format of the `.eh_frame` section is similar in format and purpose to the `.debug_frame` section which is specified in DWARF Debugging Information Format, Revision 3.0.0 (Draft). Readers are advised that there are some subtle difference, and care should be taken when comparing the two sections.

11.6.1 The `.eh_frame` section

The `.eh_frame` section shall contain 1 or more Call Frame Information (CFI) records. The number of records present shall be determined by size of the section as contained in the section header. Each CFI record contains a Common Information Entry (CIE) record followed by 1 or more Frame Description Entry (FDE) records. Both CIEs and FDEs shall be aligned to an addressing unit sized boundary.

Table 11-8 Call Frame Information Format

Common Information Entry Record
Frame Description Entry Record(s)

11.6.1.1 The Common Information Entry Format

Table 11-9 Common Information Entry Format

Length	Required
Extended Length	Optional
CIE ID	Required
Version	Required
Augmentation String	Required
Code Alignment Factor	Required
Data Alignment Factor	Required
Return Address Register	Required
Augmentation Data Length	Optional
Augmentation Data	Optional
Initial Instructions	Required
Padding	

`Length`

A 4 byte unsigned value indicating the length in bytes of the CIE structure, not including the *`Length`* field itself. If *`Length`* contains the value 0xffffffff, then the length is contained in the *`Extended Length`* field. If *`Length`* contains the value 0, then this CIE shall be considered a terminator and processing shall end.

`Extended Length`

A 8 byte unsigned value indicating the length in bytes of the CIE structure, not including the *`Length`* and *`Extended Length`* fields.

CIE ID

A 4 byte unsigned value that is used to distinguish CIE records from FDE records. This value shall always be 0, which indicates this record is a CIE.

Version

A 1 byte value that identifies the version number of the frame information structure. This value shall be 1.

Augmentation String

This value is a NUL terminated string that identifies the augmentation to the CIE or to the FDEs associated with this CIE. A zero length string indicates that no augmentation data is present. The augmentation string is case sensitive and shall be interpreted as described below.

Code Alignment Factor

An unsigned LEB128 encoded value that is factored out of all advance location instructions that are associated with this CIE or its FDEs. This value shall be multiplied by the delta argument of an adavance location instruction to obtain the new location value.

Data Alignment Factor

A signed LEB128 encoded value that is factored out of all offset instructions that are associated with this CIE or its FDEs. This value shall be multiplied by the register offset argument of an offset instruction to obtain the new offset value.

Augmentation Length

An unsigned LEB128 encoded value indicating the length in bytes of the Augmentation Data. This field is only present if the Augmentation String contains the character 'z'.

Augmentation Data

A block of data whose contents are defined by the contents of the Augmentation String as described below. This field is only present if the Augmentation String contains the character 'z'. The size of this data is given by the Augentation Length.

Initial Instructions

Initial set of Call Frame Instructions. The number of instructions is determined by the remaining space in the CIE record.

Padding

Extra bytes to align the CIE structure to an addressing unit size boundary.

11.6.1.1.1 Augmentation String Format

The Agumentation String indicates the presence of some optional fields, and how those fields should be intepreted. This string is case sensitive. Each character in the augmentation string in the CIE can be interpreted as below:

'z'

A 'z' may be present as the first character of the string. If present, the Augmentation Data field shall be present. The contents of the Augmentation

Data shall be intepreted according to other characters in the Augmentation String.

'L'

A 'L' may be present at any position after the first character of the string. This character may only be present if 'z' is the first character of the string. If present, it indicates the presence of one argument in the Augmentation Data of the CIE, and a corresponding argument in the Augmentation Data of the FDE. The argument in the Augmentation Data of the CIE is 1-byte and represents the pointer encoding used for the argument in the Augmentation Data of the FDE, which is the address of a language-specific data area (LSDA). The size of the LSDA pointer is specified by the pointer encoding used.

'P'

A 'P' may be present at any position after the first character of the string. This character may only be present if 'z' is the first character of the string. If present, it indicates the presence of two arguments in the Augmentation Data of the CIE. The first argument is 1-byte and represents the pointer encoding used for the second argument, which is the address of a *personality routine* handler. The personality routine is used to handle language and vendor-specific tasks. The system unwind library interface accesses the language-specific exception handling semantics via the pointer to the personality routine. The personality routine does not have an ABI-specific name. The size of the personality routine pointer is specified by the pointer encoding used.

'R'

A 'R' may be present at any position after the first character of the string. This character may only be present if 'z' is the first character of the string. If present, The Augmentation Data shall include a 1 byte argument that represents the pointer encoding for the address pointers used in the FDE.

11.6.1.2 The Frame Description Entry Format

Table 11-10 Frame Description Entry Format

Length	Required
Extended Length	Optional
CIE Pointer	Required
PC Begin	Required
PC Range	Required
Augmentation Data Length	Optional
Augmentation Data	Optional
Call Frame Instructions	Required
Padding	

`Length`

A 4 byte unsigned value indicating the length in bytes of the CIE structure, not including the `Length` field itself. If `Length` contains the value 0xffffffff, then the

length is contained the *Extended Length* field. If *Length* contains the value 0, then this CIE shall be considered a terminator and processing shall end.

Extended Length

A 8 byte unsigned value indicating the length in bytes of the CIE structure, not including the *Length* field itself.

CIE Pointer

A 4 byte unsigned value that when subtracted from the offset of the current FDE yields the offset of the start of the associated CIE. This value shall never be 0.

PC Begin

An encoded value that indicates the address of the initial location associated with this FDE. The encoding format is specified in the Augmentation Data.

PC Range

An absolute value that indicates the number of bytes of instructions associated with this FDE.

Augmentation Length

An unsigned LEB128 encoded value indicating the length in bytes of the Augmentation Data. This field is only present if the Augmentation String in the associated CIE contains the character 'z'.

Augmentation Data

A block of data whose contents are defined by the contents of the Augmentation String in the associated CIE as described above. This field is only present if the Augmentation String in the associated CIE contains the character 'z'. The size of this data is given by the Augentation Length.

Call Frame Instructions

A set of Call Frame Instructions.

Padding

Extra bytes to align the FDE structure to an addressing unit size boundary.

11.6.2 The `.eh_frame_hdr` section

The `.eh_frame_hdr` section contains additional information about the `.eh_frame` section. A pointer to the start of the `.eh_frame` data, and optionally, a binary search table of pointers to the `.eh_frame` records are found in this section.

Data in this section is encoded according to Section 11.5.1.

Table 11-11 `.eh_frame_hdr` Section Format

Encoding	Field
unsigned byte	version
unsigned byte	eh_frame_ptr_enc
unsigned byte	fde_count_enc
unsigned byte	table_enc

Encoding	Field
encoded	eh_frame_ptr
encoded	fde_count
	binary search table

version

Version of the `.eh_frame_hdr` format. This value shall be 1.

eh_frame_ptr_enc

The encoding format of the eh_frame_ptr field.

fde_count_enc

The encoding format of the fde_count field. A value of DW_EH_PE_omit indicates the binary search table is not present.

table_enc

The encoding format of the entries in the binary search table. A value of DW_EH_PE_omit indicates the binary search table is not present.

eh_frame_ptr

The encoded value of the pointer to the start of the `.eh_frame` section.

fde_count

The encoded value of the count of entries in the binary search table.

binary search table

A binary search table containing fde_count entries. Each entry of the table consist of two encoded values, the initial location, and the address. The entries are sorted in an increasing order by the initial location value.

11.7 Symbol Versioning

11.7.1 Introduction

This chapter describes the Symbol Versioning mechanism. All ELF objects may provide or depend on versioned symbols. Symbol Versioning is implemented by 3 section types: `SHT_GNU_versym`, `SHT_GNU_verdef`, and `SHT_GNU_verneed`.

The prefix `Elfxx` in the following descriptions and code fragments stands for either "`Elf32`" or "`Elf64`", depending on the architecture.

Versions are described by strings. The structures that are used for symbol versions also contain a member that holds the ELF hashing values of the strings. This allows for more efficient processing.

11.7.2 Symbol Version Table

The special section `.gnu.version` which has a section type of `SHT_GNU_versym` shall contain the Symbol Version Table. This section shall have the same number of entries as the Dynamic Symbol Table in the `.dynsym` section.

The `.gnu.version` section shall contain an array of elements of type `Elfxx_Half`. Each entry specifies the version defined for or required by the corresponding symbol in the Dynamic Symbol Table.

The values in the Symbol Version Table are specific to the object in which they are located. These values are identifiers that are provided by the the *`vna_other`* member of the `Elfxx_Vernaux` structure or the *`vd_ndx`* member of the `Elfxx_Verdef` structure.

The values 0 and 1 are reserved.

0

The symbol is local, not available outside the object.

1

The symbol is defined in this object and is globally available.

All other values are used to identify version strings located in one of the other Symbol Version sections. The value itself is not the version associated with the symbol. The string identified by the value defines the version of the symbol.

11.7.3 Version Definitions

The special section `.gnu.version_d` which has a section type of `SHT_GNU_verdef` shall contain symbol version definitions. The number of entries in this section shall be contained in the `DT_VERDEFNUM` entry of the Dynamic Section `.dynamic`. The `sh_link` member of the section header (see figure 4-8 in the System V ABI) shall point to the section that contains the strings referenced by this section.

The section shall contain an array of `Elfxx_Verdef` structures, as described in Figure 11-1, optionally followed by an array of `Elfxx_Verdaux` structures, as defined in Figure 11-2.

```
typedef struct {
        Elfxx_Half    vd_version;
        Elfxx_Half    vd_flags;
        Elfxx_Half    vd_ndx;
        Elfxx_Half    vd_cnt;
        Elfxx_Word    vd_hash;
        Elfxx_Word    vd_aux;
        Elfxx_Word    vd_next;
} Elfxx_Verdef;
```

Figure 11-1 Version Definition Entries

`vd_version`

Version revision. This field shall be set to `1`.

`vd_flags`

Version information flag bitmask.

`vd_ndx`

Version index numeric value referencing the SHT_GNU_versym section.

`vd_cnt`

Number of associated verdaux array entries.

vd_hash

Version name hash value (ELF hash function).

vd_aux

Offset in bytes to a corresponding entry in an array of `Elfxx_Verdaux` structures as defined in Figure 11-2

vd_next

Offset to the next verdef entry, in bytes.

```
typedef struct {
        Elfxx_Word    vda_name;
        Elfxx_Word    vda_next;
} Elfxx_Verdaux;
```

Figure 11-2 Version Definition Auxiliary Entries

vda_name

Offset to the version or dependency name string in the section header, in bytes.

vda_next

Offset to the next verdaux entry, in bytes.

11.7.4 Version Requirements

The special section `.gnu.version_r` which has a section type of `SHT_GNU_verneed` shall contain required symbol version definitions. The number of entries in this section shall be contained in the `DT_VERNEEDNUM` entry of the Dynamic Section `.dynamic`. The *sh_link* member of the section header (see figure 4-8 in System V ABI) shall point to the section that contains the strings referenced by this section.

The section shall contain an array of `Elfxx_Verneed` structures, as described in Figure 11-3, optionally followed by an array of `Elfxx_Vernaux` structures, as defined in Figure 11-4.

```
typedef struct {
        Elfxx_Half    vn_version;
        Elfxx_Half    vn_cnt;
        Elfxx_Word    vn_file;
        Elfxx_Word    vn_aux;
        Elfxx_Word    vn_next;
} Elfxx_Verneed;
```

Figure 11-3 Version Needed Entries

vn_version

Version of structure. This value is currently set to 1, and will be reset if the versioning implementation is incompatibly altered.

vn_cnt

Number of associated verneed array entries.

vn_file

Offset to the file name string in the section header, in bytes.

vn_aux

Offset to a corresponding entry in the vernaux array, in bytes.

vn_next

Offset to the next verneed entry, in bytes.

```
typedef struct {
        Elfxx_Word    vna_hash;
        Elfxx_Half    vna_flags;
        Elfxx_Half    vna_other;
        Elfxx_Word    vna_name;
        Elfxx_Word    vna_next;
} Elfxx_Vernaux;
```

Figure 11-4 Version Needed Auxiliary Entries

vna_hash

Dependency name hash value (ELF hash function).

vna_flags

Dependency information flag bitmask.

vna_other

Object file version identifier used in the .gnu.version symbol version array. Bit number 15 controls whether or not the object is hidden; if this bit is set, the object cannot be used and the static linker will ignore the symbol's presence in the object.

vna_name

Offset to the dependency name string in the section header, in bytes.

vna_next

Offset to the next vernaux entry, in bytes.

11.7.5 Startup Sequence

When loading a sharable object the system shall analyze version definition data from the loaded object to assure that it meets the version requirements of the calling object. This step is referred to as definition testing. The dynamic loader shall retrieve the entries in the caller's `Elfxx_Verneed` array and attempt to find matching definition information in the loaded `Elfxx_Verdef` table.

Each object and dependency shall be tested in turn. If a symbol definition is missing and the `vna_flags` bit for `VER_FLG_WEAK` is not set, the loader shall return an error and exit. If the `vna_flags` bit for `VER_FLG_WEAK` is set in the `Elfxx_Vernaux` entry, and the loader shall issue a warning and continue operation.

When the versions referenced by undefined symbols in the loaded object are found, version availability is certified. The test completes without error and the object shall be made available.

11.7.6 Symbol Resolution

When symbol versioning is used in an object, relocations extend definition testing beyond the simple match of symbol name strings: the version of the reference shall also equal the name of the definition.

The same index that is used in the symbol table can be referenced in the `SHT_GNU_versym` section, and the value of this index is then used to acquire name data. The corresponding requirement string is retrieved from the `Elfxx_Verneed` array, and likewise, the corresponding definition string from the `Elfxx_Verdef` table.

If the high order bit (bit number 15) of the version symbolis set, the object cannot be used and the static linker shall ignore the symbol's presence in the object.

When an object with a reference and an object with the definition are being linked, the following rules shall govern the result:

- The object with the reference and the object with the definitions both use versioning. All described matching is processed in this case. A fatal error shall be triggered when no matching definition can be found in the object whose name is the one referenced by the *vn_name* element in the `Elfxx_Verneed` entry.
- The object with the reference does not use versioning, while the object with the definitions does. In this instance, only the definitions with index numbers 1 and 2 will be used in the reference match, the same identified by the static linker as the base definition. In cases where the static linker was not used, such as in calls to `dlopen()`, a version that does not have the base definition index shall be acceptable if it is the only version for which the symbol is defined.
- The object with the reference uses versioning, but the object with the definitions specifies none. A matching symbol shall be accepted in this case. A fatal error shall be triggered if a corruption in the required symbols list obscures an outdated object file and causes a match on the object filename in the `Elfxx_Verneed` entry.
- Neither the object with the reference nor the object with the definitions use versioning. The behavior in this instance shall default to pre-existing symbol rules.

11.8 ABI note tag

Every executable shall contain a section named `.note.ABI-tag` of type `SHT_NOTE`. This section is structured as a note section as documented in the ELF spec. The section shall contain at least the following entry. The `name` field (`namesz/name`) contains the string "`GNU`". The `type` field shall be 1. The `descsz` field shall be at least 16, and the first 16 bytes of the `desc` field shall be as follows.

The first 32-bit word of the `desc` field shall be 0 (this signifies a Linux executable). The second, third, and fourth 32-bit words of the `desc` field contain the earliest compatible kernel version. For example, if the 3 words are 2, 2, and 5, this signifies a 2.2.5 kernel.

12 Dynamic Linking

12.1 Program Loading and Dynamic Linking

LSB-conforming implementations shall support the object file information and system actions that create running programs as specified in the System V ABI and System V ABI Update and as ~~supplemented~~further required by this ~~document~~specification and ~~an~~its architecture~~-~~ specific ~~LSB specification~~supplement.

Any shared object that is loaded shall contain sufficient DT_NEEDED records to satisfy the symbols on the shared library.

12.2 Program Header

In addition to the Segment Types defined in the System V ABI and System V ABI Update the following Segment Types shall also be supported.

Table 12-1 Linux Segment Types

Name	Value
PT_GNU_EH_FRAME	0x6474e550
PT_GNU_STACK	0x6474e551
PT_GNU_RELRO	0x6474e552

PT_GNU_EH_FRAME

The array element specifies the location and size of the exception handling information as defined by the .eh_frame_hdr section.

PT_GNU_STACK

The *p_flags* member specifies the permissions on the segment containing the stack and is used to indicate wether the stack should be executable. The absense of this header indicates that the stack will be executable.

PT_GNU_RELRO

The array element specifies the location and size of a segment which may be made read-only after relocation shave been processed.

12.3 Dynamic Entries

12.3.1 Introduction

As described in System V ABI, if an object file CHAPTERicipates in dynamic linking, its program header table shall have an element of type `PT_DYNAMIC`. This `segment' contains the `.dynamic` section. A special symbol, `_DYNAMIC`, labels the section, which contains an array of the following structures.

```
typedef struct {
        Elf32_Sword     d_tag;
        union {
                Elf32_Word      d_val;
                Elf32_Addr      d_ptr;
        } d_un;
} Elf32_Dyn;
```

```
extern Elf32_Dyn        _DYNAMIC[];

typedef struct {
        Elf64_Sxword    d_tag;
        union {
                Elf64_Xword     d_val;
                Elf64_Addr      d_ptr;
        } d_un;
} Elf64_Dyn;

extern Elf64_Dyn        _DYNAMIC[];
```

Figure 12-1 Dynamic Structure

For each object with this type, *d_tag* controls the interpretation of *d_un*.

12.3.2 Dynamic Entries

12.3.2.1 ELF Dynamic Entries

The following dynamic entries are defined in the System V ABI and System V ABI Update.

DT_BIND_NOW

Process relocations of object

DT_DEBUG

For debugging; unspecified

DT_FINI

Address of termination function

DT_HASH

Address of symbol hash table

DT_HIPROC

End of processor-specific

DT_INIT

Address of init function

DT_JMPREL

Address of PLT relocs

DT_LOPROC

Start of processor-specific

DT_NEEDED

Name of needed library

DT_NULL

Marks end of dynamic section

DT_PLTREL
: Type of reloc in PLT

DT_PLTRELSZ
: Size in bytes of PLT relocs

DT_REL
: Address of Rel relocs

DT_RELA
: Address of Rela relocs

DT_RELAENT
: Size of one Rela reloc

DT_RELASZ
: Total size of Rela relocs

DT_RELENT
: Size of one Rel reloc

DT_RELSZ
: Total size of Rel relocs

DT_RPATH
: Library search path

DT_SONAME
: Name of shared object

DT_STRSZ
: Size of string table

DT_STRTAB
: Address of string table

DT_SYMBOLIC
: Start symbol search here

DT_SYMENT
: Size of one symbol table entry

DT_SYMTAB
: Address of symbol table

DT_TEXTREL
: Reloc might modify .text

12.3.2.2 Additional Dynamic Entries

An LSB conforming object may also use the following additional Dynamic Entry types.

DT_ADDRRNGHI

Values from DT_ADDRRNGLO through DT_ADDRRNGHI are reserved for definition by an archLSB.

DT_ADDRRNGLO

Values from DT_ADDRRNGLO through DT_ADDRRNGHI are reserved for definition by an archLSB.

DT_AUXILIARY

Shared object to load before self

DT_FILTER

Shared object to get values from

DT_FINI_ARRAY

The address of an array of pointers to termination functions.

DT_FINI_ARRAYSZ

Size in bytes of DT_FINI_ARRAY

DT_HIOS

Values from DT_LOOS through DT_HIOS are reserved for definition by specific operating systems.

DT_INIT_ARRAY

The address of an array of pointers to initialization functions.

DT_INIT_ARRAYSZ

Size in bytes of DT_INIT_ARRAY

DT_LOOS

Values from DT_LOOS through DT_HIOS are reserved for definition by specific operating systems.

DT_NUM

Number of dynamic entry tags defined (excepting reserved ranges).

DT_POSFLAG_1

Flags for DT_* entries, effecting the following DT_* entry

DT_RELCOUNT

All Elf32_Rel R_*_RELATIVE relocations have been placed into a single block and this entry specifies the number of entries in that block. This permits ld.so.1 to streamline the processing of RELATIVE relocations.

DT_RUNPATH

null-terminated library search path string

DT_SYMINENT

Entry size of syminfo

DT_SYMINFO

Address of the Syminfo table.

DT_SYMINSZ

Size of syminfo table (in bytes)

DT_VALRNGHI

Entries which fall between DT_VALRNGHI & DT_VALRNGLO use the Dyn.d_un.d_val field of the Elf*_Dyn structure.

DT_VALRNGLO

Entries which fall between DT_VALRNGHI & DT_VALRNGLO use the Dyn.d_un.d_val field of the Elf*_Dyn structure.

DT_VERDEF

Address of version definition table

DT_VERDEFNUM

Number of version definitions

DT_VERNEED

Address of table with needed versions

DT_VERNEEDNUM

Number of needed versions

DT_VERSYM

Address of the table provided by the .gnu.version section.

III Base Libraries

13 Base Libraries

13.1 Introduction

An LSB-conforming implementation shall support the following base libraries which provide interfaces for accessing the operating system, processor and other hardware in the system.

- libc
- libm
- libgcc_s
- libdl
- librt
- libcrypt
- libpam

There are three main parts to the definition of each of these libraries.

The "Interfaces" section defines the required library name and version, and the required public symbols (interfaces and global data), as well as symbol versions, if any.

The "Interface Definitions" section provides complete or partial definitions of certain interfaces where either this specification is the source specification, or where there are variations from the source specification. If an interface definition requires one or more header files, one of those headers shall include the function prototype for the interface.

For source definitions of interfaces which include a reference to a header file, the contents of such header files form a part of the specification. The "Data Definitions" section provides the binary-level details for the header files from the source specifications, such as values for macros and enumerated types, as well as structure layouts, sizes and padding, etc. These data definitions, although presented in the form of header files for convenience, should not be taken a representing complete header files, as they are a supplement to the source specifications. Application developers should follow the guidelines of the source specifications when determining which header files need to be included to completely resolve all references.

> **Note:** While the Data Definitions supplement the source specifications, this specification itself does not require conforming implementations to supply any header files.

13.2 Program Interpreter

The Program Interpreter is specified in the appropriate architecture~~-~~ specific ~~LSB specifications~~supplement.

13.3 Interfaces for libc

Table 13-1 defines the library name and shared object name for the libc library

Table 13-1 libc Definition

Library:	libc

SONAME:	See archLSB.

The behavior of the interfaces in this library is specified by the following specifications:

[LFS] Large File Support
[LSB] ~~this specification~~This Specification
[SUSv2] SUSv2
[SUSv3] ISO POSIX (2003)
[SVID.3] SVID Issue 3
[SVID.4] SVID Issue 4

13.3.1 RPC

13.3.1.1 Interfaces for RPC

An LSB conforming implementation shall provide the generic functions for RPC specified in Table 13-2, with the full mandatory functionality as described in the referenced underlying specification.

Table 13-2 libc - RPC Function Interfaces

13.4 Data Definitions for libc

This section defines global identifiers and their values that are associated with interfaces contained in libc. These definitions are organized into groups that correspond to system headers. This convention is used as a convenience for the reader, and does not imply the existence of these headers, or their content.

~~These definitions are intended to supplement those provided in~~ Where an interface is defined as requiring a particular system header file all of the ~~referenced underlying~~data definitions for that system header file presented here shall be in effect.

This section gives data definitions to promote binary application portability, not to repeat source interface definitions available elsewhere. System providers and application developers should use this ABI to supplement - not to replace - source interface definition specifications.

This specification uses ~~ISO/IEC 9899~~the ISO C (1999) C Language as the reference programming language, and data definitions are specified in ISO C format. The C language is used here as a convenient notation. Using a C language description of these data objects does not preclude their use by other programming languages.

13.4.1 ~~ctype~~arpa/inet.h

```
~~enum~~
~~{~~
~~    _ISupper, _IScower, _ISalpha, _ISdigit, _ISxdigit, _ISspace,~~
~~_ISprint,~~
~~    _ISgraph, _ISblank, _IScntrl, _ISpunct, _ISalnum~~
~~}~~

extern uint32_t htonl(uint32_t);
extern uint16_t htons(uint16_t);
extern in_addr_t inet_addr(const char *);
extern char *inet_ntoa(struct in_addr);
extern const char *inet_ntop(int, const void *, char *, socklen_t);
extern int inet_pton(int, const char *, void *);
extern uint32_t ntohl(uint32_t);
extern uint16_t ntohs(uint16_t);
```

13.4.2 assert.h

The `assert.h` header shall define the `assert()` macro. It refers to the macro `NDEBUG`, which is not defined in this header. If `NDEBUG` is defined before the inclusion of this header, the `assert()` macro shall be defined as described below, otherwise the macro shall behave as described in `assert()` in ISO/IEC 9945 POSIX.

```
extern void __assert_fail(const char *, const char *, unsigned int,
                          const char *);
```

13.4.3 ctype.h

```
enum {
    _ISupper, _ISlower, _ISalpha, _ISdigit, _ISxdigit, _ISspace,
_ISprint,
        _ISgraph, _ISblank, _IScntrl, _ISpunct, _ISalnum
};
extern int _tolower(int);
extern int _toupper(int);
extern int isalnum(int);
extern int isalpha(int);
extern int isascii(int);
extern int iscntrl(int);
extern int isdigit(int);
extern int isgraph(int);
extern int islower(int);
extern int isprint(int);
extern int ispunct(int);
extern int isspace(int);
extern int isupper(int);
extern int isxdigit(int);
extern int toascii(int);
extern int tolower(int);
extern int toupper(int);
extern int isblank(int);
extern const unsigned short **__ctype_b_loc(void);
extern const int32_t **__ctype_toupper_loc(void);
extern const int32_t **__ctype_tolower_loc(void);
```

13.4.4 dirent.h

```
typedef struct __dirstream DIR;

struct dirent {
{
    long int d_ino;
    off_t d_off;
    unsigned short d_reclen;
    unsigned char d_type;
    char d_name[256];
}
-;
struct dirent64 {
{
    uint64_t d_ino;
    int64_t d_off;
    unsigned short d_reclen;
    unsigned char d_type;
    char d_name[256];
};
```

```
extern void rewinddir(DIR *);
extern void seekdir(DIR *, long int);
extern long int telldir(DIR *);
extern int closedir(DIR *);
extern DIR *opendir(const char *);
extern struct dirent *readdir(DIR *);
extern struct dirent64 *readdir64(DIR *);
extern int readdir_r(DIR *, struct dirent *, struct dirent **);
```

13.4.~~35~~ err.h

```
extern void err(int, const char *, ...);
extern void errx(int, const char *, ...);
extern void warn(const char *, ...);
extern void warnx(const char *, ...);
extern void error(int, int, const char *, ...);
```

13.4.6 errno.h

ISO POSIX (2003) requires that each error value shall be unique, with permission for EAGAIN and EWOULDBLOCK possibly having the same value. This specification also requires that ENOTSUP and EOPNOTSUPP have the same value.

> **Note:** A defect report against ISO POSIX (2003) has been filed to request that specification also permit these two symbols to have the same value.

```

```

13.5 Interface Definitions for libc

The ~~following~~ interfaces defined on the following pages are included in libc and are defined by this specification. Unless otherwise noted, these interfaces shall be included in the source standard.

Other interfaces listed ~~above for libc~~in Section 13.3 shall behave as described in the referenced base document.

_IO_feof

Name

`_IO_feof` — alias for feof

Synopsis

```
int _IO_feof(_IO_FILE * __fp);
```

Description

`_IO_feof()` tests the end-of-file indicator for the stream pointed to by *__fp*, returning a non-zero value if it is set.

`_IO_feof()` is not in the source standard; it is only in the binary standard.

_IO_getc

Name

`_IO_getc` — alias for getc

Synopsis

```
int _IO_getc(_IO_FILE * __fp);
```

Description

`_IO_getc()` reads the next character from *__fp* and returns it as an unsigned char cast to an int, or `EOF` on end-of-file or error.

`_IO_getc()` is not in the source standard; it is only in the binary standard.

_IO_putc

Name

_IO_putc — alias for putc

Synopsis

```
int _IO_putc(int __c, _IO_FILE * __fp);
```

Description

_IO_putc() writes the character __c, cast to an unsigned char, to __fp.

_IO_putc() is not in the source standard; it is only in the binary standard.

_IO_puts

Name

_IO_puts — alias for puts

Synopsis

```
int _IO_puts(const char * __c);
```

Description

_IO_puts() writes the string __s and a trailing newline to stdout.

_IO_puts() is not in the source standard; it is only in the binary standard.

__assert_fail

Name

__assert_fail — abort the program after false assertion

Synopsis

```
void __assert_fail(const char * assertion, const char * file, unsigned int
line, const char * function);
```

Description

The __assert_fail() function is used to implement the assert() interface of ISO POSIX (2003). The __assert_fail() function shall print the given *file* filename, *line* line number, *function* function name and a message on the standard error stream in an unspecified format, and abort program execution via the abort() function. For example:

```
a.c:10: foobar: Assertion a == b failed.
```

If *function* is NULL, __assert_fail() shall omit information about the function.

assertion, *file*, and *line* shall be non-NULL.

The __assert_fail() function is not in the source standard; it is only in the binary standard. The assert() interface is not in the binary standard; it is only in the source standard. The assert() may be implemented as a macro.

__ctype_b_loc

Name

__ctype_b_loc — accessor function for __ctype_b array for ctype functions

Synopsis

```
#include <ctype.h>
const unsigned short * * __ctype_b_loc (void);
```

Description

The __ctype_b_loc() function shall return a pointer into an array of characters in the current locale that contains characteristics for each character in the current character set. The array shall contain a total of 384 characters, and can be indexed with any signed or unsigned char (i.e. with an index value between -128 and 255). If the application is multithreaded, the array shall be local to the current thread.

This interface is not in the source standard; it is only in the binary standard.

Return Value

The __ctype_b_loc() function shall return a pointer to the array of characters to be used for the ctype() family of functions (see <ctype.h>).

__ctype_get_mb_cur_max

Name

__ctype_get_mb_cur_max — maximum length of a multibyte character in the current locale

Synopsis

```
size_t __ctype_get_mb_cur_max(void);
```

Description

__ctype_get_mb_cur_max() returns the maximum length of a multibyte character in the current locale.

__ctype_get_mb_cur_max() is not in the source standard; it is only in the binary standard.

__ctype_tolower_loc

Name

__ctype_tolower_loc — accessor function for __ctype_b_tolower array for ctype tolower() function

Synopsis

```
#include <ctype.h>
int32_t * * __ctype_tolower_loc(void);
```

Description

The __ctype_tolower_loc() function shall return a pointer into an array of characters in the current locale that contains lower case equivalents for each character in the current character set. The array shall contain a total of 384 characters, and can be indexed with any signed or unsigned char (i.e. with an index value between -128 and 255). If the application is multithreaded, the array shall be local to the current thread.

This interface is not in the source standard; it is only in the binary standard.

Return Value

The __ctype_tolower_loc() function shall return a pointer to the array of characters to be used for the ctype() family of functions (see <ctype.h>).

__ctype_toupper_loc

Name

__ctype_toupper_loc — accessor function for __ctype_b_toupper() array for ctype toupper() function

Synopsis

```
#include <ctype.h>
int32_t * * __ctype_toupper_loc(void);
```

Description

The __ctype_toupper_loc() function shall return a pointer into an array of characters in the current locale that contains upper case equivalents for each character in the current character set. The array shall contain a total of 384 characters, and can be indexed with any signed or unsigned char (i.e. with an index value between -128 and 255). If the application is multithreaded, the array shall be local to the current thread.

This interface is not in the source standard; it is only in the binary standard.

Return Value

The __ctype_toupper_loc() function shall return a pointer to the array of characters to be used for the ctype() family of functions (see <ctype.h>).

__cxa_atexit

Name

__cxa_atexit — register a function to be called by exit or when a shared library is unloaded

Synopsis

```
int __cxa_atexit(void (*func) (void *), void * arg, void * dso_handle);
```

Description

As described in the Itanium C++ ABI, __cxa_atexit() registers a destructor function to be called by exit() or when a shared library is unloaded. When a shared library is unloaded, any destructor function associated with that shared library, identified by *dso_handle*, shall be called with the single argument *arg*, and then that function shall be removed, or marked as complete, from the list of functions to run at exit(). On a call to exit(), any remaining functions registered shall be called with the single argument *arg*. Destructor functions shall always be called in the reverse order to their registration (i.e. the most recently registered function shall be called first),

The __cxa_atexit() function is used to implement atexit(), as described in ISO POSIX (2003). Calling atexit(func) from the statically linked part of an application shall be equivalent to __cxa_atexit(func, NULL, NULL).

__cxa_atexit() is not in the source standard; it is only in the binary standard.

Note: atexit() is not in the binary standard; it is only in the source standard.

__daylight

Name

__daylight — daylight savings time flag

Synopsis

```
int __daylight;
```

Description

The integer variable __daylight shall implement the daylight savings time flag daylight as specified in the ISO POSIX (2003) header file <time.h>.

__daylight is not in the source standard; it is only in the binary standard. daylight is not in the binary standard; it is only in the source standard.

__environ

Name

__environ — alias for environ - user environment

Synopsis

```
extern char * *__environ;
```

Description

__environ is an alias for environ - user environment.

__environ has the same specification as environ.

__environ is not in the source standard; it is only in the binary standard.

__errno_location

Name

__errno_location — address of errno variable

Synopsis

```
int * __errno_location(void);
```

Description

The __errno_location() function shall return the address of the errno variable for the current thread.

__errno_location() is not in the source standard; it is only in the binary standard.

__fpending

Name

__fpending — returns in bytes the amount of output pending on a stream

Synopsis

```
#include <stdio_ext.h>
size_t __fpending(FILE * stream);
```

Description

__fpending() returns the amount of output in bytes pending on a stream.

__fpending() is not in the source standard; it is only in the binary standard.

__getpagesize

Name

__getpagesize — alias for getpagesize - get current page size

Synopsis

```
int __getpagesize(void);
```

Description

__getpagesize() is an alias for getpagesize() - get current page size.

__getpagesize() has the same specification as getpagesize().

__getpagesize() is not in the source standard; it is only in the binary standard.

__getpgid

Name

__getpgid — get the process group id

Synopsis

```
pid_t __getpgid(pid_t pid);
```

Description

__getpgid() has the same specification as getpgid().

__getpgid() is not in the source standard; it is only in the binary standard.

__h_errno_location

Name

__h_errno_location — address of h_errno variable

Synopsis

```
int * __h_errno_location(void);
```

Description

__h_errno_location() returns the address of the h_errno variable, where h_errno is as specified in ISO POSIX (2003).

__h_errno_location() is not in the source standard; it is only in the binary standard. Note that h_errno itself is only in the source standard; it is not in the binary standard.

__isinf

Name

__isinf — test for infinity

Synopsis

```
int __isinf(double arg);
```

Description

__isinf() has the same specification as isinf() in ISO POSIX (2003), except that the argument type for __isinf() is known to be double.

__isinf() is not in the source standard; it is only in the binary standard.

__isinff

Name

__isinff — test for infinity

Synopsis

```
int __isinff(float arg);
```

Description

__isinff() has the same specification as isinf() in ISO POSIX (2003) except that the argument type for __isinff() is known to be float.

__isinff() is not in the source standard; it is only in the binary standard.

__isinfl

Name

__isinfl — test for infinity

Synopsis

```
int __isinfl(long double arg);
```

Description

__isinfl() has the same specification as isinf() in the ISO POSIX (2003), except that the argument type for __isinfl() is known to be long double.

__isinfl() is not in the source standard; it is only in the binary standard.

__isnan

Name

__isnan — test for infinity

Synopsis

```
int __isnan(double arg);
```

Description

__isnan() has the same specification as isnan() in ISO POSIX (2003), except that the argument type for __isnan() is known to be double.

__isnan() is not in the source standard; it is only in the binary standard.

__isnanf

Name

__isnanf — test for infinity

Synopsis

```
int __isnanf(float arg);
```

Description

__isnanf() has the same specification as isnan() in ISO POSIX (2003), except that the argument type for __isnanf() is known to be float.

__isnanf() is not in the source standard; it is only in the binary standard.

__isnanl

Name

__isnanl — test for infinity

Synopsis

```
int __isnanl(long double arg);
```

Description

__isnanl() has the same specification as isnan() in ISO POSIX (2003), except that the argument type for __isnanl() is known to be long double.

__isnanl() is not in the source standard; it is only in the binary standard.

__libc_current_sigrtmax

Name

__libc_current_sigrtmax — return number of available real-time signal with lowest priority

Synopsis

```
int __libc_current_sigrtmax(void);
```

Description

__libc_current_sigrtmax() returns the number of an available real-time signal with the lowest priority.

__libc_current_sigrtmax() is not in the source standard; it is only in the binary standard.

__libc_current_sigrtmin

Name

__libc_current_sigrtmin — return number of available real-time signal with highest priority

Synopsis

```
int __libc_current_sigrtmin(void);
```

Description

__libc_current_sigrtmin() returns the number of an available real-time signal with the highest priority.

__libc_current_sigrtmin() is not in the source standard; it is only in the binary standard.

__libc_start_main

Name

__libc_start_main — initialization routine

Synopsis

```
int __libc_start_main(int *(main) (int, char * *, char * *), int argc, char
* * ubp_av, void (*init) (void), void (*fini) (void), void (*rtld_fini)
(void), void (* stack_end));
```

Description

The __libc_start_main() function shall ~~initialize the process~~perform any necessary initialization of the execution environment, call the *main* function with appropriate arguments, and handle the return from main(). If the main() function returns, the return value shall be passed to the exit() function.

> **Note:** While this specification is intended to be implementation independent, process and library initialization may include:
>
> - performing any necessary security checks if the effective user ID is not the same as the real user ID.
> - initialize the threading subsystem.
> - registering the *rtld_fini* to release resources when this dynamic shared object exits (or is unloaded).
> - registering the *fini* handler to run at program exit.
> - calling the initializer function (*init)().
> - calling main() with appropriate arguments.
> - calling exit() with the return value from main().
>
> This list is an example only.

__libc_start_main() is not in the source standard; it is only in the binary standard.

See Also

The section on Process Initialization in each of the architecture specific supplements.

__lxstat

Name

__lxstat — inline wrapper around call to lxstat

Synopsis

```
#include <ctype.h>
int __lxstat(int version, char * __path, struct stat __statbuf);
```

Description

__lxstat() is an inline wrapper around call to lxstat().

__lxstat() is not in the source standard; it is only in the binary standard.

__mempcpy

Name

__mempcpy — copy given number of bytes of source to destination

Synopsis

```
#include <string.h>
ptr_t __mempcpy(ptr_t restrict dest, const ptr_t restrict src, size_t n);
```

Description

__mempcpy() copies *n* bytes of source to destination, returning pointer to bytes after the last written byte.

__mempcpy() is not in the source standard; it is only in the binary standard.

__rawmemchr

Name

__rawmemchr — scan memory

Synopsis

```
#include <string.h>
ptr_t __rawmemchr(const ptr_t s, int c);
```

Description

__rawmemchr() searches in *s* for *c*.

__rawmemchr() is a weak alias to rawmemchr(). It is similar to memchr(), but it has no length limit.

__rawmemchr() is not in the source standard; it is only in the binary standard.

__register_atfork

Name

__register_atfork — alias for register_atfork

Synopsis

```
int __register_atfork(void (*prepare) (void), void (*parent) (void), void
(*child) (void), void * __dso_handle);
```

Description

__register_atfork() implements pthread_atfork() as specified in ISO POSIX (2003). The additional parameter *__dso_handle* allows a shared object to pass in it's handle so that functions registered by __register_atfork() can be unregistered by the runtime when the shared object is unloaded.

__sigsetjmp

Name

__sigsetjmp — save stack context for non-local goto

Synopsis

```
int __sigsetjmp(jmp_buf env, int savemask);
```

Description

__sigsetjmp() has the same behavior as sigsetjmp() as specified by ISO POSIX (2003).

__sigsetjmp() is not in the source standard; it is only in the binary standard.

__stpcpy

Name

__stpcpy — ~~copy a string returning a pointer to its end~~alias for stpcpy

Synopsis

```
#include <string.h>
char * __stpcpy(char * dest, const char * src);
```

Description

~~__stpcpy() copies the string *src* (including the terminating /0 character) to the array *dest*. The strings may not overlap, and *dest* must be large enough to receive the copy.~~

~~Return Value~~

~~__stpcpy() returns a pointer to the end of the string *dest* (that is, the address of the terminating NULL character) rather than the beginning.~~

~~__stpcpy() has the same specification as stpcpy().~~

The __stpcpy() function has the same specification as the stpcpy().

__stpcpy() is not in the source standard; it is only in the binary standard.

__strdup

Name

__strdup — alias for strdup

Synopsis

```
char * __strdup(const char string);
```

Description

__strdup() has the same specification as strdup().

__strdup() is not in the source standard; it is only in the binary standard.

__strtod_internal

Name

__strtod_internal — underlying function for strtod

Synopsis

```
double __strtod_internal(const char * __nptr, char * * __endptr, int __group);
```

Description

__group shall be `0` or the behavior of `__strtod_internal()` is undefined.

`__strtod_internal(`*__nptr*`, `*__endptr*`, 0)()` has the same specification as `strtod(`*__nptr*`, `*__endptr*`)()`.

`__strtod_internal()` is not in the source standard; it is only in the binary standard.

__strtof_internal

Name

__strtof_internal — underlying function for strtof

Synopsis

```
float __strtof_internal(const char * __nptr, char * * __endptr, int __group);
```

Description

__group shall be `0` or the behavior of `__strtof_internal()` is undefined.

`__strtof_internal(`*__nptr*`, `*__endptr*`, 0)()` has the same specification as `strtof(`*__nptr*`, `*__endptr*`)()`.

`__strtof_internal()` is not in the source standard; it is only in the binary standard.

__strtok_r

Name

__strtok_r — alias for strtok_r

Synopsis

```
char * __strtok_r(char * restrict s, const char * restrict delim, char *
* restrict save_ptr);
```

Description

`__strtok_r()` has the same specification as `strtok_r()`.

`__strtok_r()` is not in the source standard; it is only in the binary standard.

__strtol_internal

Name

__strtol_internal — alias for strtol

Synopsis

```
long int __strtol_internal(const char * __nptr, char * * __endptr, int __base,
int __group);
```

Description

__group shall be `0` or the behavior of `__strtol_internal()` is undefined.

`__strtol_internal(`*__nptr*`, `*__endptr*`, `*__base*`, 0)` has the same specification as `strtol(`*__nptr*`, `*__endptr*`, `*__base*`)`.

`__strtol_internal()` is not in the source standard; it is only in the binary standard.

__strtold_internal

Name

__strtold_internal — underlying function for strtold

Synopsis

```
long double __strtold_internal(const char * __nptr, char * * __endptr, int
__group);
```

Description

__group shall be `0` or the behavior of `__strtold_internal()` is undefined.

`__strtold_internal(`*__nptr*`, `*__endptr*`, 0)` has the same specification as `strtold(`*__nptr*`, `*__endptr*`)`.

`__strtold_internal()` is not in the source standard; it is only in the binary standard.

__strtoll_internal

Name

__strtoll_internal — underlying function for strtoll

Synopsis

```
long long __strtoll_internal(const char * __nptr, char * * __endptr, int __base,
int __group);
```

Description

__group shall be `0` or the behavior of `__strtoll_internal()` is undefined.

`__strtoll_internal(`*__nptr*`, `*__endptr*`, `*__base*`, 0)` has the same specification as `strtoll(`*__nptr*`, `*__endptr*`, `*__base*`)`.

`__strtoll_internal()` is not in the source standard; it is only in the binary standard.

__strtoul_internal

Name

__strtoul_internal — underlying function for strtoul

Synopsis

```
unsigned long int __strtoul_internal(const char * __nptr, char * * __endptr,
int __base, int __group);
```

Description

__group shall be `0` or the behavior of `__strtoul_internal()` is undefined.

`__strtoul_internal(`*__nptr*`, `*__endptr*`, `*__base*`, 0)` has the same specification as `strtoul(`*__nptr*`, `*__endptr*`, `*__base*`)`.

`__strtoul_internal()` is not in the source standard; it is only in the binary standard.

__strtoull_internal

Name

__strtoull_internal — underlying function for strtoull

Synopsis

```
unsigned long long __strtoull_internal(const char * __nptr, char * * __endptr,
int __base, int __group);
```

Description

__group shall be 0 or the behavior of __strtoull_internal() is undefined.

__strtoull_internal(*__nptr*, *__endptr*, *__base*, 0) has the same specification as strtoull(*__nptr*, *__endptr*, *__base*).

__strtoull_internal() is not in the source standard; it is only in the binary standard.

__sysconf

Name

__sysconf — get configuration information at runtime

Synopsis

```
#include <unistd.h>
long __sysconf(int name);
```

Description

__sysconf() gets configuration information at runtime.

__sysconf() is weak alias to sysconf().

__sysconf() has the same specification as sysconf().

__sysconf() is not in the source standard; it is only in the binary standard.

__sysv_signal

Name

__sysv_signal — signal handling

Synopsis

```
__sighandler_t __sysv_signal(int sig, __sighandler_t handler);
```

Description

__sysv_signal() has the same behavior as signal() as specified by ISO POSIX (2003).

__sysv_signal() is not in the source standard; it is only in the binary standard.

__timezone

Name

— global variable containing timezone

Synopsis

```
long int __timezone;
```

Description

`__timezone()` has the same specification as `timezone()` in the *ISO POSIX (2003)*

__tzname

Name

— global variable containing the timezone

Synopsis

```
char * __tzname[2];
```

Description

`__tzname` has the same specification as `tzname` in the *ISO POSIX (2003)*.

Note that the array size of `2` is explicit in the *ISO POSIX (2003)*, but not in the *SUSv2*.

__wcstod_internal

Name

`__wcstod_internal` — underlying function for wcstod

Synopsis

```
double __wcstod_internal(const wchar_t * nptr, wchar_t * * endptr, int group);
```

Description

`group` shall be `0` or the behavior of `__wcstod_internal()` is undefined.

`__wcstod_internal(`*`nptr`*`, `*`endptr`*`, 0)` shall behave as `wcstod(`*`nptr`*`, `*`endptr`*`)` as specified by ISO POSIX (2003).

`__wcstod_internal()` is not in the source standard; it is only in the binary standard.

__wcstof_internal

Name

__wcstof_internal — underlying function for wcstof

Synopsis

```
float __wcstof_internal(const wchar_t * nptr, wchar_t * * endptr, int group);
```

Description

group shall be `0` or the behavior of `__wcstof_internal()` is undefined.

`__wcstof_internal(`*nptr*`, `*endptr*`, 0)` shall behave as `wcstof(`*nptr*`, `*endptr*`)` as specified in ISO POSIX (2003).

`__wcstof_internal()` is not in the source standard; it is only in the binary standard.

__wcstol_internal

Name

__wcstol_internal — underlying function for wcstol

Synopsis

```
long __wcstol_internal(const wchar_t * nptr, wchar_t * * endptr, int base,
int group);
```

Description

group shall be `0` or the behavior of `__wcstol_internal()` is undefined.

`__wcstol_internal(`*nptr*`, `*endptr*`, `*base*`, 0)` shall behave as `wcstol(`*nptr*`, `*endptr*`, `*base*`)` as specified by ISO POSIX (2003).

`__wcstol_internal()` is not in the source standard; it is only in the binary standard.

__wcstold_internal

Name

__wcstold_internal — underlying function for wcstold

Synopsis

```
long double __wcstold_internal(const wchar_t * nptr, wchar_t * * endptr, int
group);
```

Description

group shall be `0` or the behavior of `__wcstold_internal()` is undefined.

`__wcstold_internal(`*nptr*`, `*endptr*`, 0)` shall behave as `wcstold(`*nptr*`, `*endptr*`)` as specified by ISO POSIX (2003).

`__wcstold_internal()` is not in the source standard; it is only in the binary standard.

__wcstoul_internal

Name

__wcstoul_internal — underlying function for wcstoul

Synopsis

```
unsigned long __wcstoul_internal(const wchar_t * restrict nptr, wchar_t *
* restrict endptr, int base, int group);
```

Description

group shall be `0` or the behavior of `__wcstoul_internal()` is undefined.

`__wcstoul_internal(`*nptr*`, `*endptr*`, `*base*`, 0)()` shall behave as `wcstoul(`*nptr*`, `*endptr*`, `*base*`)()` as specified by ISO POSIX (2003).

`__wcstoul_internal()` is not in the source standard; it is only in the binary standard.

__xmknod

Name

__xmknod — make block or character special file

Synopsis

```
int __xmknod(int ver, const char * path, mode_t mode, dev_t * dev);
```

Description

The `__xmknod()` function shall implement the `mknod()` interface from ISO POSIX (2003).

The value of *ver* shall be `1` or the behavior of `__xmknod()` is undefined.

`__xmknod(1, `*path*`, `*mode*`, `*dev*`)` shall behave as `mknod(`*path*`, `*mode*`, `*dev*`)` as specified by ISO POSIX (2003).

The `__xmknod()` function is not in the source standard; it is only in the binary standard.

> **Note:** The `mknod()` function is not in the binary standard; it is only in the source standard.

__xstat

Name

__xstat — get File Status

Synopsis

```
#include <sys/stat.h>
```

```
#include <unistd.h>
int __xstat(int ver, const char * path, struct stat * stat_buf);
int __lxstat(int ver, const char * path, struct stat * stat_buf);
int __fxstat(int ver, int fildes, struct stat * stat_buf);
```

Description

The functions `__xstat()`, `__lxstat()`, and `__fxstat()` shall implement the ISO POSIX (2003) functions `stat()`, `lstat()`, and `fstat()` respectively.

ver shall be `3` or the behavior of these functions is undefined.

`__xstat(3, path, stat_buf)` shall implement `stat(path, stat_buf)` as specified by ISO POSIX (2003).

`__lxstat(3, path, stat_buf)` shall implement `lstat(path, stat_buf)` as specified by ISO POSIX (2003).

`__fxstat(3, fildes, stat_buf)` shall implement `fstat(fildes, stat_buf)` as specified by ISO POSIX (2003).

`__xstat()`, `__lxstat()`, and `__fxstat()` are not in the source standard; they are only in the binary standard.

`stat()`, `lstat()`, and `fstat()` are not in the binary standard; they are only in the source standard.

__xstat64

Name

`__xstat64` — get File Status

Synopsis

```
#define _LARGEFILE_SOURCE 1
#include <sys/stat.h>
#include <unistd.h>
int __xstat64(int ver, const char * path, struct stat64 * stat_buf);
int __lxstat64(int ver, const char * path, struct stat64 * stat_buf);
int __fxstat64(int ver, int fildes, struct stat64 * stat_buf);
```

Description

The functions `__xstat64()`, `__lxstat64()`, and `__fxstat64()` shall implement the Large File Support functions `stat64()`, `lstat64()`, and `fstat64()` respectively.

ver shall be `3` or the behavior of these functions is undefined.

`__xstat64(3, path, stat_buf)` shall behave as `stat(path, stat_buf)` as specified by Large File Support.

`__lxstat64(3, path, stat_buf)` shall behave as `lstat(path, stat_buf)` as specified by Large File Support.

`__fxstat64(3, fildes, stat_buf)` shall behave as `fstat(fildes, stat_buf)` as specified by Large File Support.

`__xstat64()`, `__lxstat64()`, and `__fxstat64()` are not in the source standard; they are only in the binary standard.

`stat64()`, `lstat64()`, and `fstat64()` are not in the binary standard; they are only in the source standard.

_environ

Name

_environ — alias for environ - user environment

Synopsis

```
extern char * *_environ;
```

Description

_environ is an alias for environ - user environment.

_nl_msg_cat_cntr

Name

_nl_msg_cat_cntr — new catalog load counter

Synopsis

```
#include <libintl.h>

extern int _nl_msg_cat_cntr;
```

Description

The global variable _nl_msg_cat_cntr is incremented each time a new catalog is loaded. This variable is only in the binary standard; it is not in the source standard.

_sys_errlist

Name

_sys_errlist — array containing the "C" locale strings used by strerror()

Synopsis

```
#include <stdio.h>

extern const char *const _sys_errlist[];
```

Description

_sys_errlist is an array containing the "C" locale strings used by strerror(). This normally should not be used directly. strerror() provides all of the needed functionality.

_sys_siglist

Name

_sys_siglist — array containing the names of the signal names

Synopsis

```
#include <signal.h>

```

```
extern const char *const _sys_siglist[NSIG];
```

Description

`_sys_siglist` is an array containing the names of the signal names.

The `_sys_siglist` array is only in the binary standard; it is not in the source standard. Applications wishing to access the names of signals should use the `strsignal()` function.

acct

Name

`acct` — switch process accounting on or off

Synopsis

```
#include <dirent.h>
int acct(const char * filename);
```

Description

When *`filename`* is the name of an existing file, `acct()` turns accounting on and appends a record to *`filename`* for each terminating process. When *`filename`* is `NULL`, `acct()` turns accounting off.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

ENOSYS

BSD process accounting has not been enabled when the operating system kernel was compiled. The kernel configuration parameter controlling this feature is *`CONFIG_BSD_PROCESS_ACCT`*.

ENOMEM

Out of memory.

EPERM

The calling process has no permission to enable process accounting.

EACCES

`filename` is not a regular file.

EIO

Error writing to the *`filename`*.

EUSERS

There are no more free file structures or we run out of memory.

adjtime

Name

`adjtime` — correct the time to allow synchronization of the system clock

Synopsis

```
#include <time.h>
int adjtime(const struct timeval * delta, struct timeval * olddelta);
```

Description

`adjtime()` makes small adjustments to the system time as returned by `gettimeofday()`(2), advancing or retarding it by the time specified by the timeval *`delta`*. If *`delta`* is negative, the clock is slowed down by incrementing it more slowly than normal until the correction is complete. If *`delta`* is positive, a larger increment than normal is used. The skew used to perform the correction is generally a fraction of one percent. Thus, the time is always a monotonically increasing function. A time correction from an earlier call to `adjtime()` may not be finished when `adjtime()` is called again. If *`olddelta`* is non-`NULL`, the structure pointed to will contain, upon return, the number of microseconds still to be corrected from the earlier call.

`adjtime()` may be used by time servers that synchronize the clocks of computers in a local area network. Such time servers would slow down the clocks of some machines and speed up the clocks of others to bring them to the average network time.

Appropriate privilege is required to adjust the system time.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

EFAULT

An argument points outside the process's allocated address space.

EPERM

The process does not have appropriate privilege.

asprintf

Name

`asprintf` — write formatted output to a dynamically allocated string

Synopsis

```
#include <stdio.h>
int asprintf(char ** restrict ptr, const char * restrict format, ...);
```

Description

The `asprintf()` function shall behave as `sprintf()`, except that the output string shall be dynamically allocated space of sufficient length to hold the resulting string. The address of this dynamically allocated string shall be stored in the location referenced by *`ptr`*.

Return Value

Refer to `fprintf()`.

Errors

Refer to `fprintf()`.

bind_textdomain_codeset

Name

`bind_textdomain_codeset` — specify encoding for message retrieval

Synopsis

```
#include <libintl.h>
char * bind_textdomain_codeset (const char * domainname , const char *
codeset );
```

Description

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogs for domain *`domainname`*. The *`codeset`* argument shall be a valid codeset name which can be used tor the *`iconv_open`* function, or a null pointer. If the *`codeset`* argument is the null pointer, then function returns the currently selected codeset for the domain with the name *`domainname`*. It shall return a null pointer if no codeset has yet been selected.

Each successive call to `bind_textdomain_codeset()` function overrrides the settings made by the preceding call with the same *`domainname`*.

The `bind_textdomain_codeset()` function shall return a pointer to a string containing the name of the selected codeset. The string shall be allocated internally in the function and shall not be changed or freed by the user.

The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and shall not be changed by the user.

Parameters

domainname

> The *`domainname`* argument is applied to the currently active LC_MESSAGE locale. It is equivalent in syntax and meaning to the *`domainname`* argument to *`textdomain`*, except that the selection of the domain is valid only for the duration of the call.

codeset

> The name of the output codeset for the selected domain, or NULL to select the current codeset.
>
> If *`domainname`* is the null pointer, or is an empty string, `bind_textdomain_codeset()` shall fail, but need not set `errno`.

Return Value

Returns the currently selected codeset name. It returns a null pointer if no codeset has yet been selected.

Errors

ENOMEM

> Insufficient memory available to allocate return value.

See Also

gettext, dgettext, ngettext, dngettext, dcgettext, dcngettext, textdomain, bindtextdomain

bindresvport

Name

`bindresvport` — bind socket to privileged IP port

Synopsis

```
#include <sys/types.h>
#include <rpc/rpc.h>
int bindresvport(int sd, struct sockaddr_in * sin);
```

Description

If the process has appropriate privilege, the `bindresvport()` function shall bind a socket to a privileged IP port.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

`EPERM`

The process did not have appropriate privilege.

`EPFNOSUPPORT`

Address of *`sin`* did not match address family of *`sd`*.

bindtextdomain

Name

bindtextdomain — specify the location of a message catalog

Synopsis

```
#include <libintl.h>
char * bindtextdomain(const char * domainname, const char * dirname);
```

Description

The bindtextdomain() shall set the the base directory of the hierarchy containing message catalogs for a given message domain.

The bindtextdomain() function specifies that the *domainname* message catalog can be found in the *dirname* directory hierarchy, rather than in the system default locale data base.

If *dirname* is not NULL, the base directory for message catalogs belonging to domain *domainname* shall be set to *dirname*. If *dirname* is NULL, the base directory for message catalogs shall not be altered.

The function shall make copies of the argument strings as needed.

dirname can be an absolute or relative pathname.

> **Note:** Applications that wish to use chdir() should always use absolute pathnames to avoid misadvertently selecting the wrong or non-existant directory.

If *domainname* is the null pointer, or is an empty string, bindtextdomain() shall fail, but need not set errno.

The bindtextdomain() function shall return a pointer to a string containing the name of the selected directory. The string shall be allocated internally in the function and shall not be changed or freed by the user.

Return Value

On success, bindtextdomain() shall return a pointer to a string containing the directory pathname currently bound to the domain. On failure, a NULL pointer is returned, and the global variable errno may be set to indicate the error.

Errors

ENOMEM

Insufficient memory was available.

See Also

gettext, dgettext, ngettext, dngettext, dcgettext, dcngettext, textdomain, bind_textdomain_codeset

cfmakeraw

Name

`cfmakeraw` — get and set terminal attributes

Synopsis

```
#include <termios.h>
void cfmakeraw(struct termios * termios_p);
```

Description

The `cfmakeraw()` function shall set the attributes of the `termios` structure referenced by *`termios_p`* as follows:

```
termios_p->c_iflag &= ~(IGNBRK|BRKINT|PARMRK|ISTRIP
                        |INLCR|IGNCR|ICRNL|IXON);

termios_p->c_oflag &= ~OPOST;

termios_p->c_lflag &= ~(ECHO|ECHONL|ICANON|ISIG|IEXTEN);

termios_p->c_cflag &= ~(CSIZE|PARENB);

termios_p->c_cflag |= CS8;
```

`termios_p` shall point to a `termios` structure that contains the following members:

```
tcflag_t c_iflag;      /* input modes */
tcflag_t c_oflag;      /* output modes */
tcflag_t c_cflag;      /* control modes */
tcflag_t c_lflag;      /* local modes */
cc_t c_cc[NCCS];       /* control chars */
```

cfsetspeed

Name

`cfsetspeed` — set terminal input and output data rate

Synopsis

```
#include <termios.h>
int cfsetspeed(struct termios *t, speed_t speed);
```

Description

`cfsetspeed()` sets the baud rate values in the `termios` structure. The effects of the function on the terminal as described below do not become effective, nor are all errors detected, until the `tcsetattr()` function is called. Certain values for baud rates set in `termios` and passed to `tcsetattr()` have special meanings.

Getting and Setting the Baud Rate

Input and output baud rates are found in the `termios` structure. The unsigned integer *`speed_t`* is typdef'd in the include file `termios.h`. The value of the integer corresponds directly to the baud rate being represented; however, the following symbolic values are defined.

```
#define B0      0
#define B50     50
#define B75     75
#define B110    110
#define B134    134
#define B150    150
#define B200    200
#define B300    300
#define B600    600
#define B1200   1200
#define B1800   1800
#define B2400   2400
#define B4800   4800
#define B9600   9600
#define B19200  19200
#define B38400  38400
#ifndef _POSIX_SOURCE
#define EXTA    19200
#define EXTB    38400
#endif  /*_POSIX_SOURCE */
```

`cfsetspeed()` sets both the input and output baud rates in the `termios` structure referenced by `t` to *`speed`*.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

EINVAL

Invalid *`speed`* argument

daemon

Name

daemon — run in the background

Synopsis

```
#include <unistd.h>
int daemon(int nochdir, int noclose);
```

Description

The daemon() function shall create a new process, detached from the controlling terminal. If successful, the calling process shall exit and the new process shall continue to execute the application in the background. If *nochdir* evaluates to true, the current directory shall not be changed. Otherwise, daemon() shall change the current working directory to the root (`/'). If *noclose* evaluates to true the standard input, standard output, and standard error file descriptors shall not be altered. Otherwise, daemon() shall close the standard input, standard output and standard error file descriptors and reopen them attached to /dev/null.

Return Value

On error, -1 is returned, and the global variable errno is set to any of the errors specified for the library functions fork() and setsid().

dcgettext

Name

dcgettext — perform domain and category specific lookup in message catalog

Synopsis

```
#include <libintl.h>
```

```
#include <locale.h>
char * dcgettext(const char * domainname, const char * msgid, int category);
```

Description

The `dcgettext()` function is a domain specified version of `gettext()`.

The `dcgettext()` function shall lookup the translation in the current locale of the message identified by *`msgid`* in the domain specified by *`domainname`* and in the locale category specified by *`category`*. If *`domainname`* is NULL, the current default domain shall be used. The *`msgid`* argument shall be a NULL-terminated string to be matched in the catalogue. *`category`* shall specify the locale category to be used for retrieving message strings. The category parameter shall be one of *`LC_CTYPE`*, *`LC_COLLATE`*, *`LC_MESSAGES`*, *`LC_MONETARY`*, *`LC_NUMERIC`*, or *`LC_TIME`*. The default domain shall not be changed by a call to `dcgettext()`.

Return Value

If a translation was found in one of the specified catalogs, it shall be converted to the current locale's codeset and returned. The resulting NULL-terminated string shall be allocated by the dcgettext function, and must not be modified or freed. If no translation was found, or category was invalid, *`msgid`* shall be returned.

Errors

`dcgettext()` shall not modify the `errno` global variable.

See Also

gettext, dgettext, ngettext, dngettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset

dcngettext

Name

`dcngettext` — perform domain and category specific lookup in message catalog with plural

Synopsis

```
#include <libintl.h>
```

```
#include <locale.h>
char * dcngettext(const char * domainname, const char * msgid1, const char
* msgid2, unsigned long int n, int category);
```

Description

The `dcngettext()` function is a domain specific version of gettext, capable of returning either a singular or plural form of the message. The `dcngettext()` function shall lookup the translation in the current locale of the message identified by *`msgid1`* in the domain specified by *`domainname`* and in the locale category specified by *`category`*. If *`domainname`* is NULL, the current default domain shall be used. The *`msgid1`* argument shall be a NULL-terminated string to be matched in the catalogue. *`category`* shall specify the locale category to be used for retrieving message strings. The *`category`* parameter shall be one of *`LC_CTYPE`*, *`LC_COLLATE`*, *`LC_MESSAGES`*, *`LC_MONETARY`*, *`LC_NUMERIC`*, or *`LC_TIME`*. The default domain shall not be changed by a call to `dcngettext()`. If *`n`* is 1 then the singular version of the message is returned, otherwise one of the plural forms is returned, depending on the value of *`n`* and the current locale settings.

Return Value

If a translation corresponding to the value of *`n`* was found in one of the specified catalogs for *`msgid1`*, it shall be converted to the current locale's codeset and returned. The resulting NULL-terminated string shall be allocated by the `dcngettext()` function, and must not be modified or freed. If no translation was found, or *`category`* was invalid, *`msgid1`* shall be returned if *`n`* has the value 1, otherwise *`msgid2`* shall be returned.

Errors

`dcngettext()` shall not modify the `errno` global variable.

See Also

gettext, dgettext, ngettext, dngettext, dcgettext, textdomain, bindtextdomain, bind_textdomain_codeset

dgettext

Name

`dgettext` — perform lookup in message catalog for the current LC_MESSAGES locale

Synopsis

```
#include <libintl.h>
char * dgettext(const char * domainname, const char * msgid);
```

Description

`dgettext()` is a domain specified version of `gettext()`.

~~Parameters~~

~~domainname~~

~~——~~The `dgettext()` ~~applies~~ function shall search the currently selected message catalogs in the domain *`domainname`* for a string identified by the string *`msgid`*. If a string is located, that string shall be returned. The domain specified by *`domainname`* applies to the currently active `LC_MESSAGE` locale. ~~This~~The default domain shall not be changed by a call to `dgettext()`.

> **Note:** The usage of *`domainanme`* is equivalent in syntax and meaning to the `textdomain()` function's application of *`domainname`*, except that the selection of the domain in `dgettext()` is valid only for the duration of the call.

~~msgid~~

~~——a `NULL`-terminated string to be matched in the catalogue with respect~~The `dgettext()` function is equivalent to ~~a specific domain and the current locale~~`dcgettext(domainname, msgid, LC_MESSAGES)`.

Return Value

On success of a *`msgid`* query, the translated `NULL`-terminated string is returned. On error, the original *`msgid`* is returned. The length of the string returned is undetermined until `dgettext()` is called.

Errors

`dgettext()` shall not modify the `errno` global variable.

See Also

gettext, dgettext, ngettext, dngettext, dcgettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset

dngettext

Name

dngettext — perform lookup in message catalog for the current locale

Synopsis

```
#include <libintl.h>
char * dngettext(const char * domainname, const char * msgid1, const char *
msgid2, unsigned long int n);
```

Description

dngettext() shall be equivalent to a call to

```
dcngettext(domainname, msgid1, msgid2, n, LC_MESSAGES)
```

See dcngettext() for more information.

See Also

gettext, dgettext, ngettext, dcgettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset

duplocale

Name

duplocale — provide new handle for selection of locale

Synopsis

```
#include <locale.h>
locale_t duplocale(locale_t locale);
```

Description

The duplocale() function shall provide a new locale object based on the locale object provided in *locale*, suitable for use in the newlocale() or uselocale() functions. The new object may be released by calling freelocale().

Return Value

On success, the duplocale() function shall return a locale object. Otherwise, it shall return NULL, and set errno to indicate the error.

Errors

The duplocale() function shall fail if:

ENOMEM

Insufficient memory.

See Also

setlocale(), freelocale(), newlocale(), uselocale()

err

Name

`err` — display formatted error messages

Synopsis

```
#include <err.h>
void err(int eval, const char * fmt, ...);
```

Description

The `err()` function shall display a formatted error message on the standard error stream. First, `err()` shall write the last component of the program name, a colon character, and a space character. If *`fmt`* is non-NULL, it shall be used as a format string for the `printf()` family of functions, and `err()` shall write the formatted message, a colon character, and a space. Finally, the error message string affiliated with the current value of the global variable `errno` shall be written, followed by a newline character.

The `err()` function shall not return, the program shall terminate with the exit value of *`eval`*.

See Also

`error()`, `errx()`

Return Value

None.

Errors

None.

error

Name

`error` — print error message

Synopsis

```
#include <err.h>
void error(int exitstatus, int errnum, const char * format, ...);
```

Description

`error()` shall print a message to standard error.

`error()` shall build the message from the following elements in their specified order:

1. the program name. If the application has provided a function named `error_print_progname()`, `error()` shall call this to supply the program name; otherwise, `error()` uses the content of the global variable `program_name`.
2. the colon and space characters, then the result of using the printf-style *`format`* and the optional arguments.
3. if *`errnum`* is nonzero, `error()` shall add the colon and space characters, then the result of `strerror(errnum)`.
4. a newline.

If *`exitstatus`* is nonzero, `error()` shall call `exit(exitstatus)`.

See Also

`err()`, `errx()`

errx

Name

errx — display formatted error message and exit

Synopsis

```
#include <err.h>
void errx(int eval, const char * fmt, ...);
```

Description

The errx() function shall display a formatted error message on the standard error stream. The last component of the program name, a colon character, and a space shall be output. If *fmt* is non-NULL, it shall be used as the format string for the printf() family of functions, and the formatted error message, a colon character, and a space shall be output. The output shall be followed by a newline character.

errx() does not return, but shall exit with the value of *eval*.

Return Value

None.

Errors

None.

See Also

error(), err()

fcntl

Name

fcntl — file control

Description

fcntl() is as specified in ISO POSIX (2003), but with differences as listed below.

Implementation may set O_LARGEFILE

According to ISO POSIX (2003), only an application sets fcntl() flags, for example O_LARGEFILE. However, this specification also allows an implementation to set the O_LARGEFILE flag in the case where the programming environment is one of _POSIX_V6_ILP32_OFFBIG, _POSIX_V6_LP64_OFF64, _POSIX_V6_LPBIG_OFFBIG. See **getconf** and **c99** in ISO POSIX (2003) for a description of these environments. Thus, calling fcntl() with the *F_GETFL* command may return O_LARGEFILE as well as flags explicitly set by the application in the case that both the implementation and the application support an off_t of at least 64 bits.

fflush_unlocked

Name

`fflush_unlocked` — non thread safe fflush

Description

`fflush_unlocked()` is the same as `fflush()` except that it need not be thread safe. That is, it may only be invoked in the ways which are legal for `getc_unlocked()`.

fgetwc_unlocked

Name

`fgetwc_unlocked` — non thread safe fgetwc

Description

`fgetwc_unlocked()` is the same as `fgetwc()` except that it need not be thread safe. That is, it may only be invoked in the ways which are legal for `getc_unlocked()`.

flock

Name

`flock` — apply or remove an advisory lock on an open file

Synopsis

```
int flock(int fd, int operation);
```

Description

`flock()` applies or removes an advisory lock on the open file *`fd`*. Valid *`operation`* types are:

LOCK_SH

: Shared lock. More than one process may hold a shared lock for a given file at a given time.

LOCK_EX

: Exclusive lock. Only one process may hold an exclusive lock for a given file at a given time.

LOCK_UN

: Unlock.

LOCK_NB

: Don't block when locking. May be specified (by *or*ing) along with one of the other operations.

A single file may not simultaneously have both shared and exclusive locks.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

EWOULDBLOCK

: The file is locked and the `LOCK_NB` flag was selected.

freelocale

Name

4430 freelocale — free a locale object

Synopsis

4431 ```
#include <locale.h>
```
4432 ```
void freelocale(locale_t locale);
```

Description

4433 The freelocale() function shall free the locale object *locale*, and release any
4434 resources associated with it.

Return Value

4435 None.

Errors

4436 None defined.

See Also

4437 setlocale(), newlocale(), duplocale(), uselocale()

fscanf

Name

4438 fscanf — convert formatted input

Description

4439 The scanf() family of functions shall behave as described in ISO POSIX (2003),
4440 except as noted below.

Differences

4441 The %s, %S and %[conversion specifiers shall accept an option length modifier a,
4442 which shall cause a memory buffer to be allocated to hold the string converted. In
4443 such a case, the argument corresponding to the conversion specifier should be a
4444 reference to a pointer value that will receive a pointer to the allocated buffer. If there
4445 is insufficient memory to allocate a buffer, the function may set errno to ENOMEM
4446 and a conversion error results.

4447 **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier
4448 for hexadecimal float values. While this conversion specifier should be supported, a
4449 format specifier such as "%aseconds" will have a different meaning on an LSB
4450 conforming system.

fwscanf

Name

4451 `fwscanf` — convert formatted input

Description

4452 The `scanf()` family of functions shall behave as described in ISO POSIX (2003),
4453 except as noted below.

Differences

4454 The `%s`, `%S` and `%[` conversion specifiers shall accept an option length modifier `a`,
4455 which shall cause a memory buffer to be allocated to hold the string converted. In
4456 such a case, the argument corresponding to the conversion specifier should be a
4457 reference to a pointer value that will receive a pointer to the allocated buffer. If there
4458 is insufficient memory to allocate a buffer, the function may set `errno` to ENOMEM
4459 and a conversion error results.

4460 **Note:** This directly conflicts with the ISO C (1999) usage of `%a` as a conversion specifier
4461 for hexadecimal float values. While this conversion specifier should be supported, a
4462 format specifier such as `"%aseconds"` will have a different meaning on an LSB
4463 conforming system.

getgrouplist

Name

getgrouplist — get network group entry

Synopsis

```
#include <grp.h>
int getgrouplist(const char * user, gid_t group, gid_t * groups, int *
ngroups);
```

Description

The getgrouplist() function shall fill in the array *groups* with the supplementary groups for the user specified by *user*. On entry, *ngroups* shall refer to an integer containing the maximum number of gid_t members in the *groups* array. The group *group* shall also be included. On success, the value referred to by *ngroups* shall be updated to contain the number of gid_t objects copied.

Return Value

On success, if there was sufficient room to copy all the supplementatry group identifiers to the array identified by *groups*, getgrouplist() shall return the number of gid_t objects copied, and the value referenced by *ngroups* shall be updated. If there was not sufficient room to copy all the supplementary group identifiers, grouplist() shall return -1, and update the value referenced by *ngroups* to the number actually copied.

If *user* does not refer to a valid user on the system, getgrouplist() shall return 0, and set the value referenced by *ngroups* to 0.

Errors

None defined.

See Also

getgroups()

getloadavg

Name

getloadavg — get system load averages

Synopsis

```
#include <stdlib.h>
int getloadavg(double loadavg[], int nelem);
```

Description

getloadavg() returns the number of processes in the system run queue averaged over various periods of time. Up to *nelem* samples are retrieved and assigned to successive elements of *loadavg*[]. The system imposes a maximum of 3 samples, representing averages over the last 1, 5, and 15 minutes, respectively.

getopt

Name

`getopt` — parse command line options

Synopsis

```
#include <unistd.h>
int getopt(int argc, char * const argv[], const char * optstring);

extern char *optarg;
```

```
extern int optind, opterr, optopt;
```

Description

The `getopt()` function shall parse command line arguments as described in ISO POSIX (2003), with the following exceptions, where LSB and POSIX specifications vary. LSB systems shall implement the modified behaviors described below.

Argument Ordering

The `getopt()` function can process command line arguments referenced by *`argv`* in one of three ways:

PERMUTE

the order of arguments in *`argv`* is altered so that all options (and their arguments) are moved in front of all of the operands. This is the default behavior.

Note: This behavior has undefined results if *`argv`* is not modifiable. This is to support historic behavior predating the use of const and ISO C (1999). The function prototype was aligned with ISO POSIX (2003) despite the fact that it modifies *`argv`*, and the library maintainers are unwilling to change this.

REQUIRE_ORDER

The arguments in *`argv`* are processed in exactly the order given, and option processing stops when the first non-option argument is reached, or when the element of argv is "--". This ordering can be enforced either by setting the environment variable `POSIXLY_CORRECT`, or by setting the first character of *`optstring`* to '+'.

RETURN_IN_ORDER

The order of arguments is not altered, and all arguments are processed. Non-option arguments (operands) are handled as if they were the argument to an option with the value 1 ('\001'). This ordering is selected by setting the first character of *`optstring`* to '-';

Option Characteristics

LSB specifies that:

- an element of *`argv`* that starts with "-" (and is not exactly "-" or "--") is an option element.
- characters of an option element, aside from the initial "-", are option characters.

POSIX specifies that:

- applications using `getopt()` shall obey the following syntax guidelines:
  - option name is a single alphanumeric character from the portable character set
  - option is preceded by the '-' delimiter character
  - options without option-arguments should be accepted when grouped behind one '-' delimiter
  - each option and option-argument is a separate argument
  - option-arguments are not optional
  - all options should precede operands on the command line

4534 • the argument "--" is accepted as a delimiter indicating the end of options and the
4535 consideration of subsequent arguments, if any, as operands

4536 • historical implementations of `getopt()` support other characters as options as an
4537 allowed extension, but applications that use extensions are not maximally
4538 portable.

4539 • support for multi-byte option characters is only possible when such characters can
4540 be represented as type `int`.

4541 • applications that call any utility with a first operand starting with '-' should
4542 usually specify "--" to mark the end of the options. Standard utilities that do not
4543 support this guideline indicate that fact in the OPTIONS section of the utility
4544 description.

4545 ### Extensions

4546 *LSB* specifies that:

4547 • if a character is followed by two colons, the option takes an optional argument; if
4548 there is text in the current *`argv`* element, it is returned in *`optarg`*, otherwise
4549 *`optarg`* is set to `0`.

4550 • if *`optstring`* contains `W` followed by a semi-colon (;), then `-W foo` is treated as the
4551 long option `--foo`.

4552 **Note:** See `getopt_long()` for a description of long options.

4553 • The first character of *`optstring`* shall modify the behavior of `getopt()` as follows:

4554 • if the first character is '+', then `REQUIRE_ORDER` processing shall be in effect (see
4555 above)

4556 • if the first character is '-', then `RETURN_IN_ORDER` processing shall be in effect
4557 (see above)

4558 • if the first character is ':', then `getopt()` shall return ':' instead of '?' to indicate a
4559 missing option argument, and shall not print any diagnostic message to `stderr`.

4560 *POSIX* specifies that:

4561 • the `-W` option is reserved for implementation extensions.

4562 ### Return Values

4563 *LSB* specifies the following additional `getopt()` return values:

4564 • '\001' is returned if `RETURN_IN_ORDER` argument ordering is in effect, and the next
4565 argument is an operand, not an option. The argument is available in `optarg`.

4566 Any other return value has the same meaning as for *POSIX*.

4567 *POSIX* specifies the following `getopt()` return values:

4568 • the next option character is returned, if found successfully.

4569 • ':' is returned if a parameter is missing for one of the options and the first character
4570 of `optstring` is ':'.

4571 • '?' is returned if an unknown option character not in `optstring` is encountered, or
4572 if `getopt()` detects a missing argument and the first character of `optstring` is not
4573 ':'.

4574 • -1 is returned for the end of the option list.

Environment Variables

LSB specifies that:

- if the variable `POSIXLY_CORRECT` is set, option processing stops as soon as a non-option argument is encountered.
- the variable *`_[PID]`*`_GNU_nonoption_argv_flags_` (where *`[PID]`* is the process ID for the current process), contains a space separated list of arguments that should not be treated as arguments even though they appear to be so.

  Rationale: This was used by bash 2.0 to communicate to *GNU* libc which arguments resulted from wildcard expansion and so should not be considered as options. This behavior was removed in bash version 2.01, but the support remains in *GNU* libc.

  This behavior is DEPRECATED in this version of the LSB; future revisions of this specification may not include this requirement.

getopt_long

Name

`getopt_long` — parse command line options

Synopsis

```
#define _GNU_SOURCE
#include <getopt.h>
int getopt_long(int argc, char * const argv[], const char * opstring, const
struct option * longopts, int * longindex);
```

Description

`getopt_long()` works like `getopt()` except that it also accepts long options, started out by two dashes. Long option names may be abbreviated if the abbreviation is unique or is an exact match for some defined option. A long option may take a parameter, of the form `--arg=param` or `--arg param`.

`longopts` is a pointer to the first element of an array of struct `option` declared in `getopt.h` as:

```
struct option {
          const char *name;
          int has_arg;
          int *flag;
          int val;
};
```

The fields in this structure have the following meaning:

`name`

The name of the long option.

`has_arg`

One of:

`argument` (or 0) if the option does not take an argument,
`uired_argument` (or 1) if the option requires an argument, or
`ional_argument` (or 2) if the option takes an optional argument.

`flag`

specifies how results are returned for a long option. If flag is `NULL`, then `getopt_long()` shall return *`val`*. (For example, the calling program may set val to the equivalent short option character.) Otherwise, `getopt_long()` returns 0, and *`flag`* shall point to a variable which shall be set to *`val`* if the option is found, but left unchanged if the option is not found.

`val`

The value to return, or to load into the variable pointed to by flag.

Return Value

`getopt_long()` returns the option character if a short option was found successfully, or ":" if there was a missing parameter for one of the options, or "?" for an unknown option character, or -1 for the end of the option list.

For a long option, `getopt_long()` returns *`val`* if *`flag`* is `NULL`, and 0 otherwise. Error and -1 returns are the same as for `getopt()`, plus "?" for an ambiguous match or an extraneous parameter.

getopt_long_only

Name

`getopt_long_only` — parse command line options

Synopsis

```
#define _GNU_SOURCE
```

```
#include <getopt.h>
int getopt_long_only(int argc, char * const argv[], const char * optstring,
const struct option * longopts, int * longindex);
```

Description

`getopt_long_only()` is like `getopt_long()`, but "-" as well as "--" can indicate a long option. If an option that starts with "-" (not "--") doesn't match a long option, but does match a short option, it is parsed as a short option instead.

> **Note:** The `getopt_long_only()` function is intended only for supporting certain programs whose command line syntax was designed before the Utility Syntax Guidelines of ISO POSIX (2003) were developed. New programs should generally call `getopt_long()` instead, which provides the --option syntax for long options, which is preferred by GNU and consistent with ISO POSIX (2003).

Return Value

`getopt_long_only()` returns the option character if the option was found successfully, or ":" if there was a missing parameter for one of the options, or "?" for an unknown option character, or -1 for the end of the option list.

`getopt_long_only()` also returns the option character when a short option is recognized. For a long option, they return val if flag is `NULL`, and 0 otherwise. Error and -1 returns are the same as for `getopt()`, plus "?" for an ambiguous match or an extraneous parameter.

getsockopt

Name

`getsockopt` — get socket options

Synopsis

```
#include <sys/socket.h>
```

```
#include <netinet/ip.h>
int getsockopt(int socket, int level, int option_name, void * restrict
option_value, socklen_t * restrict option_len);
```

Description

The `getsockopt()` function shall behave as specified in *ISO POSIX (2003)*, with the following extensions.

IP Protocol Level Options

If the *`level`* parameter is `IPPROTO_IP`, the following values shall be supported for *`option_name`* (see RFC 791:Internet Protocol for further details):

`IP_OPTIONS`

Get the Internet Protocol options sent with every packet from this socket. The *`option_value`* shall point to a memory buffer in which the options shall be placed; on entry *`option_len`* shall point to an integer value indicating the maximum size of the memory buffer, in bytes. On successful return, the value referenced by *`option_len`* shall be updated to the size of data copied to the buffer. For IPv4, the maximum length of options is 40 bytes.

`IP_TTL`

Get the current unicast Internet Protocol Time To Live value used when sending packets with this socket. The *`option_value`* shall point to a buffer large enough to hold the time to live value (at least 1 byte), and *`option_len`* shall point to an integer value holding the maximum size of that buffer. On successful return, the value referenced by *`option_len`* shall be updated to contain the number of bytes copied into the buffer, which shall be no larger than the initial value, and *`option_value`* shall point to an integer containing the time to live value.

`IP_TOS`

Get the Internet Protocol type of service indicator used when sending packets with this socket. The *`option_value`* shall point to a buffer large enough to hold the type of service indicator (at least 1 byte), and *`option_len`* shall point to an integer value holding the maximum size of that buffer. On successful return, the value referenced by *`option_len`* shall be updated to contain the number of bytes copied into the buffer, which shall be no larger than the initial value, and *`option_value`* shall point to an integer containing the time to live value.

gettext

Name

gettext — search message catalogs for a string

Synopsis

```
#include <libintl.h>
char * gettext(const char * msgid);
```

Description

The gettext() function shall search the currently selected message catalogs for a string identified by the string *msgid*. If a string is located, that string shall be returned.

The gettext() function is equivalent to dcgettext(NULL, msgid, LC_MESSAGES).

Return Value

If a string is found in the currently selected message catalogs for *msgid*, then a pointer to that string shall be returned. Otherwise, a pointer to *msgid* shall be returned.

Applications shall not modify the string returned by gettext().

Errors

None.

The gettext() function shall not modify errno.

See Also

dgettext, ngettext, dngettext, dcgettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset

getutent

Name

`getutent` — access user accounting database entries

Synopsis

```
#include <utmp.h>
struct utmp *getutent(void);
```

Description

The `getutent()` function shall read the next entry from the user accounting database.

Return Value

Upon successful completion, `getutent()` shall return a pointer to a `utmp` structure containing a copy of the requested entry in the user accounting database. Otherwise, a null pointer shall be returned. The return value may point to a static area which is overwritten by a subsequent call to `getutent()`.

Errors

None defined.

getutent_r

Name

`getutent_r` — access user accounting database entries

Synopsis

```
int getutent_r(struct utmp * buffer, struct utmp ** result);
```

Description

The `getutent_r()` function is a reentrant version of the `getutent()` function. On entry, *`buffer`* should point to a user supplied buffer to which the next entry in the database will be copied, and *`result`* should point to a location where the result will be stored.

Return Value

On success, `getutent_r()` shall return 0 and set the location referenced by *`result`* to a pointer to *`buffer`*. Otherwise, `getutent_r()` shall return `-1` and set the location referenced by *`result`* to `NULL`.

glob64

Name

glob64 — find pathnames matching a pattern (Large File Support)

Synopsis

```
#include <glob.h>
int glob64(const char * pattern, int flags, int (*errfunc) (const char *, int),
glob64_t * pglob);
```

Description

The glob64() function is a large-file version of the glob() defined in ISO POSIX (2003). It shall search for pathnames matching *pattern* according to the rules used by the shell, /bin/sh. No tilde expansion or parameter substitution is done; see wordexp().

The results of a glob64() call are stored in the structure pointed to by *pglob,* which is a glob64_t declared in glob.h with the following members:

```
typedef struct
{
  size_t gl_pathc;
  char **gl_pathv;
  size_t gl_offs;
  int gl_flags;
  void (*gl_closedir) (void *);
  struct dirent64 *(*gl_readdir64) (void *);
  void *(*gl_opendir) (const char *);
  int (*gl_lstat) (const char *, struct stat *);
  int (*gl_stat) (const char *, struct stat *);
}
```

4733 `glob64_t;`

4734 Structure members with the same name as corresponding members of a `glob_t` as
4735 defined in ISO POSIX (2003) shall have the same purpose.

4736 Other members are defined as follows:

4737 *`gl_flags`*

4738 reserved for internal use

4739 *`gl_closedir`*

4740 pointer to a function capable of closing a directory opened by *`gl_opendir`*

4741 *`gl_readdir64`*

4742 pointer to a function capable of reading entries in a large directory

4743 *`gl_opendir`*

4744 pointer to a function capable of opening a large directory

4745 *`gl_stat`*

4746 pointer to a function capable of returning file status for a large file

4747 *`gl_lstat`*

4748 pointer to a function capable of returning file status information for a large file
4749 or symbolic link

4750 A large file or large directory is one with a size which cannot be represented by a
4751 variable of type off_t.

Return Value

4752 On success, 0 is returned. Other possible returns are:

4753 GLOB_NOSPACE

4754 out of memory

4755 GLOB_ABORTED

4756 read error

4757 GLOB_NOMATCH

4758 no match found

globfree64

Name

globfree64 — free memory from glob64() (Large File Support)

Synopsis

```
#include <glob.h>
void globfree64(glob64_t * pglob);
```

Description

globfree64() frees the dynamically allocated storage from an earlier call to glob64().

globfree64() is a 64-bit version of globfree().

initgroups

Name

initgroups — initialize the supplementary group access list

Synopsis

```
#include <grp.h>
#include <sys/types.h>
int initgroups(const char * user, gid_t group);
```

Description

If the process has appropriate privilege, the initgroups() function shall initialize the Supplementary Group IDs for the current process by reading the group database and using all groups of which *user* is a member. The additional group *group* is also added to the list.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable errno is set appropriately.

Errors

EPERM

The calling process does not have sufficient privileges.

ENOMEM

Insufficient memory to allocate group information structure.

See Also

setgroups()

ioctl

Name

ioctl — control device

Synopsis

```
#include <sys/ioctl.h>
int ioctl (int fildes , int request , ...);
```

Description

The ioctl() function shall manipulate the underlying device parameters of special files. *fildes* shall be an open file descriptor referring to a special file. The ioctl() function shall take three parameters; the type and value of the third parameter is dependent on the device and *request*.

Conforming LSB applications shall not call ioctl() except in situations explicitly stated in this specification.

Return Value

On success, 0 is returned. An ioctl() may use the return value as an output parameter and return a non-negative value on success. On error, -1 is returned and the global variable errno is set appropriately.

Errors

EBADF

fildes is not a valid descriptor.

EFAULT

The third parameter references an inaccessible memory area.

ENOTTY

fildes is not associated with a character special device.

ENOTTY

The specified request does not apply to the kind of object that *fildes* references.

EINVAL

request or the third parameter is not valid.

Relationship to POSIX (Informative)

It should be noted that ISO POSIX (2003) contains an interface named ioctl(). The LSB only defines behavior when *fildes* refers to a socket (see sockio) or terminal device (see ttyio), while ISO POSIX (2003) only defines behavior when *fildes* refers to a STREAMS device. An implementation may support both behaviors; the LSB does not require any STREAMS support.

sockio

Name

`sockio` — socket ioctl commands

Synopsis

```
#include <sys/ioctl.h>
#include <sys/socket.h>
#include <net/if.h>
```

```
#include <netinet/in.h>
int ioctl(int sockfd, int request, void * argp);
```

Description

Socket `ioctl()` commands are a subset of the `ioctl()` calls, which can perform a variety of functions on sockets. *`sockfd`* shall be an open file descriptor referring to a socket (see the `socket()` or `accept()` functions).

Socket `ioctl()` commands apply to the underlying network interfaces, and affect the entire system, not just the file descriptor used to issue the `ioctl()`.

The following values for *`request`* are accepted:

`SIOCGIFCONF` (Deprecated)

Get the interface configuration list for the system.

Note: The `SIOCGIFCONF` interface is superceded by the `if_nameindex()` family of functions (see ISO POSIX (2003)). A future version of this specification may withdraw this value for *`request`*.

`argp` shall point to a `ifconf` structure, as described in `<net/if.h>`. Before calling, the caller shall set the *`ifc_ifcu.ifcu_req`* field to point to an array of `ifreq` structures, and set *`ifc_len`* to the size in bytes of this allocated array. Upon return, *`ifc_len`* will contain the size in bytes of the array which was actually used. If it is the same as the length upon calling, the caller should assume that the array was too small and try again with a larger array.

On success, `SIOCGIFCONF` shall return a nonnegative value.

Rationale: Historical UNIX systems disagree on the meaning of the return value.

`SIOCGIFFLAGS`

Get the interface flags for the indicated interface. *`argp`* shall point to a `ifreq` structure. Before calling, the caller should fill in the *`ifr_name`* field with the interface name, and upon return, the *`ifr_ifru.ifru_flags`* field is set with the interface flags.

`SIOCGIFADDR`

Get the interface address for the given interface. *`argp`* shall point to a `ifreq` structure. Before calling, the caller should fill in the *`ifr_name`* field with the interface name, and upon return, the *`ifr_ifru.ifru_addr`* field is set with the interface address.

`SIOCGIFBRDADDR`

Get the interface broadcast address for the given interface. *`argp`* shall point to a `ifreq` structure. Before calling, the caller should fill in the *`ifr_name`* field with the interface name, and upon return, the *`ifr_ifru.ifru_broadcast`* field is set with the interface broadcast address.

`SIOCGIFNETMASK`

Get the network mask for the given interface. *`argp`* shall point to a `ifreq` structure. Before calling, the caller should fill in the *`ifr_name`* field with the interface name, and upon return, the *`ifr_ifru.ifru_netmask`* field is set with the network mask.

4853 SIOCGIFMTU

4854 Get the Maximum Transmission Unit (MTU) size for the given interface. *argp*
4855 shall point to a ifreq structure. Before calling, the caller should fill in the
4856 *ifr_name* field with the interface name, and upon return, the
4857 *ifr_ifru.ifru_mtu* field is set with the MTU.

4858 FIONREAD

4859 Get the amount of queued unread data in the receive buffer. *argp* shall point to
4860 an integer where the result is to be placed.

4861 **Note:** Some implementations may also support the use of FIONREAD on other types of file
4862 descriptor. However, the LSB only ~~speicifess~~specifies its behavior for a socket related
4863 file descriptor.

Return Value

4864 On success, if *request* is SIOCGIFCONF, a non-negative integer shall be returned. If
4865 request is not SIOCGIFCONF, on success 0 is returned. On error, -1 is returned and
4866 the global variable errno is set appropriately.

Errors

4867 EBADF

4868 *sockfd* is not a valid descriptor.

4869 EFAULT

4870 *argp* references an inaccessible memory area.

4871 ENOTTY

4872 The specified *request* does not apply to the kind of object that the descriptor
4873 *sockfd* references.

4874 EINVAL

4875 Either *request* or *argp* is invalid.

4876 ENOTCONN

4877 The operation is only defined on a connected socket, but the socket wasn't
4878 connected.

ttyio

Name

4879 ttyio — tty ioctl commands

Synopsis

4880 #include <sys/ioctl.h>

```
#include <fcntl.h>
int ioctl(int fd, unsigned long request, int * argp);
```

Description

Tty *ioctl* commands are a subset of the `ioctl()` calls, which can perform a variety of functions on tty devices. *`fd`* shall be an open file descriptor referring to a terminal device.

The following `ioctl()`s are provided:

`TIOCGWINSZ`

Get the size attributes of the terminal or pseudo-terminal identified by *`fd`*. On entry, *`argp`* shall reference a `winsize` structure. On return, the structure will have *`ws_row`* set to the number of rows of text (i.e. lines of text) that can be viewed on the device, and *`ws_col`* set to the number of columns (i.e. text width).

Note: The number of columns stored in *`ws_col`* assumes that the terminal device is using a mono-spaced font.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

EBADF

`fd` is not a valid descriptor.

EFAULT

`argp` references an inaccessible memory area.

EINVAL

`request` and *`argp`* are not valid.

kill

Name

kill — send a signal

Synopsis

```
#include <signal.h>
int kill(pid_t pid, int sig);
```

Description

kill() is as specified in the *ISO POSIX (2003)*, but with differences as listed below.

Process ID -1 doesn't affect calling process

If *pid* is specified as -1, *sig* shall not be sent to the calling process. Other than this, the rules in the *ISO POSIX (2003)* apply.

> **Rationale:** This was a deliberate Linus decision after an unpopular experiment in including the calling process in the 2.5.1 kernel. See "What does it mean to signal everybody?", Linux Weekly News, 20 December 2001, http://lwn.net/2001/1220/kernel.php3

link

Name

link — create a link to a file

Synopsis

```
#include <unistd.h>
int link(const char * path1, const char * path2);
```

Description

The link() function shall behave as specified in *ISO POSIX (2003)*, except with differences as listed below.

Need Not Follow Symlinks

ISO POSIX (2003) specifies that pathname resolution shall follow symbolic links during pathname resolution unless the function is required to act on the symbolic link itself, or certain arguments direct that the function act on the symbolic link itself. The link() function in ISO POSIX (2003) contains no such requirement to operate on a symbolic link. However, a conforming LSB implementation need not follow a symbolic link for the *path1* argument.

mbsnrtowcs

Name

`mbsnrtowcs` — convert a multibyte string to a wide character string

Synopsis

```
#include <wchar.h>
size_t mbsnrtowcs(wchar_t * dest, const char * * src, size_t nms, size_t len,
mbstate_t * ps);
```

Description

`mbsnrtowcs()` is like `mbsrtowcs()`, except that the number of bytes to be converted, starting at *`src`*, is limited to *`nms`*.

If *`dest`* is not a `NULL` pointer, `mbsnrtowcs()` converts at most *`nms`* bytes from the multibyte string *`src`* to a wide-character string starting at *`dest`*. At most, *`len`* wide characters are written to *`dest`*. The state *`ps`* is updated.

The conversion is effectively performed by repeatedly calling:

```
mbrtowc(dest, *src, n, ps)
```

where *n* is some positive number, as long as this call succeeds, and then incrementing *dest* by one and *src* by the number of bytes consumed.

The conversion can stop for three reasons:

- An invalid multibyte sequence has been encountered. In this case *src* is left pointing to the invalid multibyte sequence, (size_t)(-1) is returned, and `errno` is set to EILSEQ.
- The *nms* limit forces a stop, or *len* non-L'\0' wide characters have been stored at *dest*. In this case, *src* is left pointing to the next multibyte sequence to be converted, and the number of wide characters written to *dest* is returned.
- The multibyte string has been completely converted, including the terminating '\0' (which has the side effect of bringing back *ps* to the initial state). In this case, *src* is set to `NULL`, and the number of wide characters written to *dest*, excluding the terminating L'\0' character, is returned.

If *dest* is `NULL`, *len* is ignored, and the conversion proceeds as above, except that the converted wide characters are not written out to memory, and that no destination length limit exists.

In both of the above cases, if *ps* is a `NULL` pointer, a static anonymous state only known to `mbsnrtowcs()` is used instead.

The programmer shall ensure that there is room for at least *len* wide characters at *dest*.

Return Value

`mbsnrtowcs()` returns the number of wide characters that make up the converted part of the wide character string, not including the terminating null wide character. If an invalid multibyte sequence was encountered, (size_t)(-1) is returned, and the global variable `errno` is set to EILSEQ.

Notes

The behavior of `mbsnrtowcs()` depends on the `LC_CTYPE` category of the current locale.

Passing NULL as *ps* is not multi-thread safe.

memmem

Name

`memmem` — locate bytes

Synopsis

```
#define _GNU_SOURCE
```

```
#include <string.h>
void * memmem(const void * haystack, size_t haystacklen, const void * needle,
size_t needlelen);
```

Description

`memmem()` finds the start of the first occurrence of the byte array referenced by *`needle`* of length *`needlelen`* in the memory area *`haystack`* of length *`haystacklen`*.

Return Value

`memmem()` returns a pointer to the beginning of the byte array, or `NULL` if the byte array is not found.

Notes

Earlier versions of the C library (prior to glibc 2.1) contained a `memmem()` with various problems, and application developers should treat this function with care.

memrchr

Name

`memrchr` — scan memory for a character

Synopsis

```
#include <string.h>
void * memrchr(const void * s, int c, size_t n);
```

Description

The `memrchr()` function shall locate the last occurence of *`c`* (converted to an unsigned char) in the initial *`n`* bytes (each interpreted as an unsigned char) of the object pointed to by *`s`*.

Return Value

The `memrchr()` shall return a pointer to the located byte, or a null pointer if the byte does not occur in the object.

Errors

No errors are defined.

See Also

`memchr()`

newlocale

Name

newlocale — allocate a locale object

Synopsis

```
#include <locale.h>
locale_t newlocale(int category_mask, const char * locale, locale_t base);
```

Description

The newlocale() function shall initialize a locale object. If *base* is NULL, then newlocale() shall first allocate the object; otherwise it shall use the locale object referenced by *base*.

The object shall be initialized for the locale named by *locale*, and for the categories selected in *category_mask*. The *category_mask* value is a bitwise inclusive OR of the required LC_*name*_MASK values, or the value LC_ALL_MASK.

Return Value

On success, the newlocale() function shall return the initialized locale object. Otherwise, it shall return NULL, and set errno to indicate the error.

Errors

The newlocale() function shall fail if:

ENOMEM

Insufficient memory.

EINVAL

An invalid *category_mask* was provided, or the *locale* was NULL.

Application Usage (Informative)

The only portable way to allocate a locale object is to call newlocale() with a NULL *base*. The allocated object may be reinitialized to a new locale by passing it back to newlocale(). The new object may be released by calling freelocale().

See Also

setlocale(), freelocale(), duplocale(), uselocale()

ngettext

Name

ngettext — search message catalogs for plural string

Synopsis

```
#include <libintl.h>
char * ngettext(const char * msgid1, const char * msgid2, unsigned long int
n);
```

Description

The ngettext() function shall search the currently selected message catalogs for a string matching the singular string *msgid1*. If a string is located, and if *n* is 1, that string shall be returned. If *n* is not 1, a pluralized version (dependent on *n*) of the string shall be returned.

The ngettext() function is equivalent to dcngettext(NULL, msgid1, msgid2, n, LC_MESSAGES)().

Return Value

If a string is found in the currently selected message catalogs for *msgid1*, then if *n* is 1 a pointer to the located string shall be returned. If *n* is not 1, a pointer to an appropriately pluralized version of the string shall be returned. If no message could be found in the currently selected mesage catalogs, then if *n* is 1, a pointer to *msgid1* shall be returned, otherwise a pointer to *msgid2* shall be returned.

Applications shall not modify the string returned by ngettext().

Errors

None.

The ngettext() function shall not modify errno.

See Also

gettext, dgettext, ngettext, dngettext, dcgettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset

pmap_getport

Name

`pmap_getport` — find the port number assigned to a service registered with a portmapper.

Synopsis

```
#include <rpc/pmap_clnt.h>
u_short * pmap_getport(struct sockaddr_in * address, const u_long program,
const u_long * version, u_int protocol);
```

Description

The `pmap_getport()` function shall return the port number assigned to a service registered with a RPC Binding service running on a given target system, using the protocol described in RFC 1833: Binding Protocols for ONC RPC Version 2. The `pmap_getport()` function shall be called given the RPC program number *`program`*, the program version *`version`*, and transport protocol *`protocol`*. Conforming implementations shall support both `IPPROTO_UDP` and `IPPROTO_TCP` protocols. On entry, *`address`* shall specify the address of the system on which the portmapper to be contacted resides. The value of `address->sin_port` shall be ignored, and the standard value for the portmapper port shall always be used.

> **Note:** Security and network restrictions may prevent a conforming application from contacting a remote RPC Binding Service.

Return Value

On success, the `pmap_getport()` function shall return the port number in host byte order of the RPC application registered with the remote portmapper. On failure, if either the program was not registered or the remote portmapper service could not be reached, the `pmap_getport()` function shall return 0. If the remote portmap service could not be reached, the status is left in the global variable `rpc_createerr`.

pmap_set

Name

`pmap_set` — establishes mapping to machine's RPC Bind service.

Synopsis

```
#include <rpc/pmap_clnt.h>
bool_t pmap_set(const u_long program, const u_long version, int protocol,
u_short port);
```

Description

`pmap_set()` establishes a mapping between the triple *`[program, version, protocol]`* and *`port`* on the machine's RPC Bind service. The value of *`protocol`* is most likely `IPPROTO_UDP` or `IPPROTO_TCP`. Automatically done by `svc_register()`.

Return Value

`pmap_set()` returns ~~1~~non-zero if it suceeds, 0 otherwise.

pmap_unset

Name

`pmap_unset` — destroys RPC Binding

Synopsis

```
#include <rpc/~~rpc~~pmap_clnt.h>

bool_t pmap_unset(u_long progNum, u_long versNum);
```

Description

As a user interface to the RPC Bind service, `pmap_unset()` destroys all mapping between the triple [*progNum*,*versNum*, *] and `ports` on the machine's RPC Bind service.

Return Value

`pmap_unset()` returns ~~1~~ non-zero if it succeeds, zero otherwise.

psignal

Name

`psignal` — print signal message

Synopsis

```
#include <signal.h>
void psignal(int sig, const char * s);

extern const char *const sys_siglist[]
```

Description

The `psignal()` function shall display a message on the `stderr` stream. If *s* is not the null pointer, and does not point to an empty string (e.g. `"\0"`), the message shall consist of the string *s*, a colon, a space, and a string describing the signal number *sig*; otherwise `psignal()` shall display only a message describing the signal number *sig*. If *sig* is invalid, the message displayed shall indicate an unknown signal.

The array `sys_siglist` holds the signal description strings indexed by signal number.

Return Value

`psignal()` returns no value.

regexec

Name

regexec — regular expression matching

Description

The regexec() function shall behave as specified in *ISO POSIX (2003)*, except with differences as listed below.

Differences

Certain aspects of regular expression matching are optional; see Internationalization and Regular Expressions.

scanf

Name

scanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

setbuffer

Name

setbuffer — stream buffering operation

Synopsis

```
#include <stdio.h>
void setbuffer(FILE * stream, char * buf, size_t size);
```

Description

setbuffer() is an alias for the call to setvbuf(). It works the same, except that the size of the buffer in setbuffer() is up to the caller, rather than being determined by the default *BUFSIZ*.

setgroups

Name

`setgroups` — set list of supplementary group IDs

Synopsis

```
#include <grp.h>
int setgroups(size_t size, const gid_t * list);
```

Description

If the process has appropriate privilege, the `setgroups()` function shall set the supplementary group IDs for the current process. *`list`* shall reference an array of *`size`* group IDs. A process may have at most `NGROUPS_MAX` supplementary group IDs.

Return Value

On successful completion, 0 is returned. On error, -1 is returned and the `errno` is set to indicate the error.

Errors

EFAULT

`list` has an invalid address.

EPERM

The process does not have appropriate privileges.

EINVAL

`size` is greater than `NGROUPS_MAX`.

sethostname

Name

`sethostname` — set host name

Synopsis

```
#include <unistd.h>
#include <sys/param.h.h>
```

```
#include <sys/utsname.h>
int sethostname(const char * name, size_t len);
```

Description

If the process has appropriate privileges, the `sethostname()` function shall change the host name for the current macine. The *name* shall point to a null-terminated string of at most *len* bytes that holds the new hostname.

If the symbol `HOST_NAME_MAX` is defined, or if `sysconf(_SC_HOST_NAME_MAX)()` returns a value greater than 0, this value shall represent the maximum length of the new hostname. Otherwise, if the symbol `MAXHOSTLEN` is defined, this value shall represent the maximum length for the new hostname. If none of these values are defined, the maximum length shall be the size of the *nodename* field of the `utsname` structure.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

EINVAL

len is negative or larger than the maximum allowed size.

EPERM

the process did not have appropriate privilege.

EFAULT

name is an invalid address.

Rationale

ISO POSIX (2003) guarantees that:

> Maximum length of a host name (not including the terminating null) as returned from the `gethostname()` function shall be at least 255 bytes.

The glibc C library does not currently define `HOST_NAME_MAX`, and although it provides the name `_SC_HOST_NAME_MAX` a call to `sysconf()` returns -1 and does not alter `errno` in this case (indicating that there is no restriction on the hostname length). However, the glibc manual idicates that some implementations may have `MAXHOSTNAMELEN` as a means of detecting the maximum length, while the Linux kernel at release 2.4 and 2.6 stores this hostname in the `utsname` structure. While the glibc manual suggests simply shortening the name until `sethostname()` succeeds, the LSB requires that one of the first four mechanisms works. Future versions of glibc may provide a more reasonable result from `sysconf`(`_SC_HOST_NAME_MAX`).

setsockopt

Name

`setsockopt` — set socket options

Synopsis

```
#include <sys/socket.h>
```

```
#include <netinet/ip.h>
int setsockopt(int socket, int level, int option_name, const void *
option_value, socklen_t option_len);
```

Description

The `setsockopt()` function shall behave as specified in *ISO POSIX (2003)*, with the following extensions.

IP Protocol Level Options

If the *`level`* parameter is `IPPROTO_IP`, the following values shall be supported for *`option_name`* (see RFC 791:Internet Protocol for further details):

`IP_OPTIONS`

Set the Internet Protocol options sent with every packet from this socket. The *`option_value`* shall point to a memory buffer containing the options and *`option_len`* shall contain the size in bytes of that buffer. For IPv4, the maximum length of options is 40 bytes.

`IP_TOS`

Set the Type of Service flags to use when sending packets with this socket. The *`option_value`* shall point to a value containing the type of service value. The least significant two bits of the value shall contain the new Type of Service indicator. Use of other bits in the value is unspecified. The *`option_len`* parameter shall hold the size, in bytes, of the buffer referred to by *`option_value`*.

`IP_TTL`

Set the current unicast Internet Protocol Time To Live value used when sending packets with this socket. The *`option_value`* shall point to a value containing the time to live value, which shall be between 1 and 255. The *`option_len`* parameter shall hold the size, in bytes, of the buffer referred to by *`option_value`*.

`IP_MULTICAST_TTL`

Sets the Time To Live value of outgoing multicast packets for this socket. *`optval`* shall point to an integer which contains the new TTL value. If the new TTL value is `-1`, the implementation should use an unspecified default TTL value. If the new TTL value is out of the range of acceptable values (0-255), `setsockopt()` shall return `-1` and set `errno` to indicate the error.

`IP_MULTICAST_LOOP`

Sets a boolean flag indicating whether multicast packets originating locally should be looped back to the local sockets. *`optval`* shall point to an integer which contains the new flag value.

`IP_ADD_MEMBERSHIP`

Join a multicast group. *`optval`* shall point to a `ip_mreq` structure. Before calling, the caller should fill in the *`imr_multiaddr`* field with the multicast group address and the *`imr_address`* field with the address of the local interface. If *`imr_address`* is set to INADDR_ANY, then an appropriate interface is chosen by the system.

`IP_DROP_MEMBERSHIP`

Leave a multicast group. *`optval`* shall point to a `ip_mreq` structure containing the same values as were used with `IP_ADD_MEMBERSHIP`.

`IP_MULTICAST_IF`

Set the local device for a multicast socket. *`optval`* shall point to a `ip_mreq` structure initialized in the same manner as with `IP_ADD_MEMBERSHIP`.

The `ip_mreq` structure contains two `struct in_addr` fields: *`imr_multiaddr`* and *`imr_address`*.

Return Value

On success, 0 is returned. On error, -1 is returned and the global variable `errno` is set appropriately.

Errors

As defined in ISO POSIX (2003).

setutent

Name

`setutent` — access user accounting database entries

Synopsis

```
#include <utmp.h>
void setutent(void);
```

Description

The `setutent()` function shall reset the user accounting database such that the next call to `getutent()` shall return the first record in the database. It is recommended to call it before any of the other functions that operate on the user accounting databases (e.g. `getutent()`)

Return Value

None.

sigandset

Name

`sigandset` — build a new signal set by combining the two input sets using logical AND

Synopsis

```
#include <signal.h>
int sigandset(sigset_t * set, const sigset_t * left, const sigset_t * right);
```

Description

The `sigandset()` shall combine the two signal sets referenced by *`left`* and *`right`*, using a logical AND operation, and shall place the result in the location referenced by *`set`*, The resulting signal set shall contain only signals that are in both the set referenced by *`left`* and the set referenced by *`right`*.

Return Value

On success, `sigandset()` shall return 0. Otherise, `sigandset()` shall return -1 and set `errno` to indicate the error.

Errors

`EINVAL`

One or more of *`set`*, *`left`*, or *`right`* was a null pointer.

See Also

`sigorset()`

sigisemptyset

Name

`sigisemptyset` — check for empty signal set

Synopsis

```
#include <signal.h>
int sigisemptyset(const sigset_t * set);
```

Description

The `sigisemptyset()` function shall check for empty signal set referenced by *`set`*.

Return Value

The `sigisemptyset()` function shall return a positive non-zero value if the signal set referenced by *`set`* is empty, or zero if this set is empty. On error, `sigisemptyset()` shall return -1 and set `errno` to indicate the error.

Errors

`EINVAL`

`set` is a null pointer.

sigorset

Name

`sigorset` — build a new signal set by combining the two input sets using logical OR

Synopsis

```
#include <signal.h>
int sigorset(sigset_t * set, const sigset_t * left, const sigset_t * right);
```

Description

The `sigorset()` shall combine the two signal sets referenced by *`left`* and *`right`*, using a logical OR operation, and shall place the result in the location referenced by *`set`*, The resulting signal set shall contain only signals that are in either the set referenced by *`left`* or the set referenced by *`right`*.

Return Value

On success, `sigorset()` shall return 0. Otherise, `sigorset()` shall return -1 and set `errno` to indicate the error.

Errors

`EINVAL`

One or more of *`set`*, *`left`*, or *`right`* was a null pointer.

See Also

`sigandset()`

sigreturn

Name

`sigreturn` — return from signal handler and cleanup stack frame

Synopsis

```
int sigreturn(struct sigcontext * scp);
```

Description

The `sigreturn()` function is used by the system to cleanup after a signal handler has returned. This function is not in the source standard; it is only in the binary standard.

Return Value

`sigreturn()` never returns.

sscanf

Name

sscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

stime

Name

stime — set time

Synopsis

```
#define _SVID_SOURCE
#include <time.h>
int stime(const time_t * t);
```

Description

If the process has appropriate privilege, the stime() function shall set the system's idea of the time and date. Time, referenced by *t*, is measured in seconds from the epoch (defined in ISO POSIX (2003) as 00:00:00 UTC January 1, 1970).

Return Value

On success, stime() shall return 0. Otherwise, stime() shall return -1 and errno shall be set to indicate the error.

Errors

EPERM

The process does not have appropriate privilege.

EINVAL

t is a null pointer.

stpcpy

Name

`stpcpy` — copy a string returning a pointer to its end

Synopsis

```
#include <string.h>
char * stpcpy(char * restrict dest, const char * restrict src);
```

Description

The `stpcpy()` function shall copy the string pointed to by *`src`* (including the terminating null character) to the array pointed to by *`dest`*. The strings may not overlap, and the destination string *`dest`* shall be large enough to receive the copy.

Return Value

`stpcpy()` returns a pointer to the end of the string *`dest`* (that is, the address of the terminating null character) rather than the beginning.

Example

This program uses `stpcpy()` to concatenate `foo` and `bar` to produce `foobar`, which it then prints.

```
#include <string.h>

int
main (void)
{
  char buffer[256];
  char *to = buffer;
  to = stpcpy (to, "foo");
  to = stpcpy (to, "bar");
  printf ("%s\n", buffer);
}
```

stpncpy

Name

`stpncpy` — copy a fixed-size string, returning a pointer to its end

Synopsis

```
#include <string.h>
char * stpncpy(char * restrict dest, const char * restrict src, size_t n);
```

Description

The `stpncpy()` function shall copy at most *n* characters from the string pointed to by *src*, including the terminating null character, to the array pointed to by *dest*. Exactly *n* characters are written at *dest*. If the length `strlen()`*(src)* is smaller than *n*, the remaining characters in *dest* are filled with '\0' characters. If the length `strlen`*(src)* is greater than or equal to *n*, *dest* will not be null terminated.

The strings may not overlap.

The programmer shall ensure that there is room for at least *n* characters at *dest*.

Return Value

The `stpncpy()` function shall return a pointer to the terminating NULL in *dest*, or, if *dest* is not NULL-terminated, *dest* + *n*.

strcasestr

Name

`strcasestr` — locate a substring ignoring case

Synopsis

```
#include <string.h>
char * strcasestr(const char * s1, const char * s2);
```

Description

The `strcasestr()` shall behave as `strstr()`, except that it shall ignore the case of both strings. The `strcasestr()` function shall be locale aware; that is `strcasestr()` shall behave as if both strings had been converted to lower case in the current locale before the comparison is performed.

Return Value

Upon successful completion, `strcasestr()` shall return a pointer to the located string or a null pointer if the string is not found. If *s2* points to a string with zero length, the function shall return *s1*.

strerror_r

Name

`strerror_r` — reentrant version of strerror

Synopsis

```
#include <string.h>
char * strerror_r(int errnum, char * buf, size_t buflen);
```

Description

The `strerror_r()` shall behave as specified in ISO POSIX (2003), except as described below.

Returns String, not Error Value

The `strerror_r()` function shall return a pointer to the string corresponding to *`errno`*. The returned pointer may point within the buffer *`buf`* (at most *`buflen`* bytes).

Return Value

On success, `strerror_r()` shall return a pointer to the generated message string (determined by the setting of the LC_MESSAGES category in the current locale). Otherwise, `strerror_r()` shall return the string corresponding to "Unknown error".

strndup

Name

`strndup` — return a malloc'd copy of at most the specified number of bytes of a string

Synopsis

```
#include <string.h>
char * strndup(const char * string, size_t n);
```

Description

The `strndup()` function shall return a `malloc()`'d copy of at most *`n`* bytes of *`string`*. The resultant string shall be terminated even if no NULL terminator appears before *`string`*+*`n`*.

Return Value

On success, `strndup()` shall return a pointer to a newly allocated block of memory containing a copy of at most *`n`* bytes of *`string`*. Otherwise, `strndup()` shall return NULL and set `errno` to indicate the error.

Errors

`ENOMEM`

Insufficient memory available.

strnlen

Name

5347 strnlen — determine the length of a fixed-size string

Synopsis

5348 ```
#include <string.h>
```
5349 ```
size_t strnlen(const char * s, size_t maxlen);
```

Description

5350 strnlen() returns the number of characters in the string *s*, not including the
5351 terminating \0 character, but at most *maxlen*. In doing this, strnlen() looks only at
5352 the first *maxlen* characters at *s* and never beyond *s* + *maxlen*.

Return Value

5353 strnlen() returns strlen*(s)*, if that is less than *maxlen*, or *maxlen* if there is no \0
5354 character among the first *maxlen* characters pointed to by *s*.

strptime

Name

5355 strptime — parse a time string

Description

5356 The strptime() shall behave as specified in the *ISO POSIX (2003)* with differences
5357 as listed below.

Number of leading zeroes may be limited

5358

5359 The *ISO POSIX (2003)* specifies fields for which "leading zeros are permitted but not
5360 required"; however, applications shall not expect to be able to supply more leading
5361 zeroes for these fields than would be implied by the range of the field.
5362 Implementations may choose to either match an input with excess leading zeroes, or
5363 treat this as a non-matching input. For example, %j has a range of 001 to 366, so 0, 00,
5364 000, 001, and 045 are acceptable inputs, but inputs such as 0000, 0366 and the like
5365 are not.

Rationale

5366 *glibc* developers consider it appropriate behavior to forbid excess leading zeroes.
5367 When trying to parse a given input against several format strings, forbidding excess
5368 leading zeroes could be helpful. For example, if one matches 0011-12-26
5369 against %m-%d-%Y and then against %Y-%m-%d, it seems useful for the first match to
5370 fail, as it would be perverse to parse that date as November 12, year 26. The second
5371 pattern parses it as December 26, year 11.

5372 The *ISO POSIX (2003)* is not explicit that an unlimited number of leading zeroes are
5373 required, although it may imply this. The LSB explicitly allows implementations to
5374 have either behavior. Future versions of this standard may require implementations
5375 to forbid excess leading zeroes.

5376 An Interpretation Request is currently pending against ISO POSIX (2003) for this
5377 matter.

strsep

Name

`strsep` — extract token from string

Synopsis

```
#include <string.h>
char * strsep(char * * stringp, const char * delim);
```

Description

The `strsep()` function shall find the first token in the string referenced by the pointer *`stringp`*, using the characters in *`delim`* as delimiters.

If *`stringp`* is NULL, `strsep()` shall return NULL and do nothing else.

If *`stringp`* is non-NULL, `strsep()` shall find the first token in the string referenced by *`stringp`*, where tokens are delimited by characters in the string *`delim`*. This token shall be terminated with a \0 character by overwriting the delimiter, and *`stringp`* shall be updated to point past the token. In case no delimiter was found, the token is taken to be the entire string referenced by *`stringp`*, and the location referenced by *`stringp`* is made NULL.

Return Value

`strsep()` shall return a pointer to the beginning of the token.

Notes

The `strsep()` function was introduced as a replacement for `strtok()`, since the latter cannot handle empty fields. However, `strtok()` conforms to ISO C (1999) and to ISO POSIX (2003) and hence is more portable.

See Also

`strtok()`, `strtok_r()`.

strsignal

Name

`strsignal` — return string describing signal

Synopsis

```
#define _GNU_SOURCE
```

```
#include <string.h>
char * strsignal(int sig);

extern const char * const sys_siglist[];
```

Description

The `strsignal()` function shall return a pointer to a string describing the signal number *`sig`*. The string can only be used until the next call to `strsignal()`.

The array `sys_siglist` holds the signal description strings indexed by signal number. This array should not be accessed directly by applications.

Return Value

If *`sig`* is a valid signal number, `strsignal()` shall return a pointer to the appropriate description string. Otherwise, `strsignal()` shall return either a pointer to the string `"unknown signal"`, or a null pointer.

Although the function is not declared as returning a pointer to a constant character string, applications shall not modify the returned string.

strtoq

Name

`strtoq` — convert string value to a long or quad_t integer

Synopsis

```
#include <sys/types.h>
#include <stdlib.h>
```

```
#include <limits.h>
long long strtoq(const char * nptr, char * * endptr, int base);
```

Description

`strtoq()` converts the string *`nptr`* to a quadt value. The conversion is done according to the given base, which shall be between `2` and `36` inclusive, or be the special value `0`.

`nptr` may begin with an arbitrary amount of white space (as determined by `isspace()`), followed by a single optional `+` or `-` sign character. If *`base`* is `0` or `16`, the string may then include a 0x prefix, and the number will be read in base 16; otherwise, a `0` base is taken as 10 (decimal), unless the next character is `0`, in which case it is taken as 8 (octal).

The remainder of the string is converted to a long value in the obvious manner, stopping at the first character which is not a valid digit in the given base. (In bases above 10, the letter `A` in either upper or lower case represents 10, `B` represents 11, and so forth, with `Z` representing 35.)

Return Value

`strtoq()` returns the result of the conversion, unless the value would underflow or overflow. If an underflow occurs, `strtoq()` returns `QUAD_MIN`. If an overflow occurs, `strtoq()` returns `QUAD_MAX`. In both cases, the global variable `errno` is set to ERANGE.

Errors

ERANGE

The given string was out of range; the value converted has been clamped.

strtouq

Name

`strtouq` — convert a string to an unsigned long long

Synopsis

```
#include <sys/types.h>
#include <stdlib.h>
```

```
#include <limits.h>
unsigned long long strtouq(const char * nptr, char * * endptr, int base);
```

Description

`strtouq()` converts the string *`nptr`* to an unsigned long long value. The conversion is done according to the given base, which shall be between `2` and `36` inclusive, or be the special value `0`.

`nptr` may begin with an arbitrary amount of white space (as determined by `isspace()`), followed by a single optional `+` or `-` sign character. If *`base`* is `0` or `16`, the string may then include a 0x prefix, and the number will be read in base 16; otherwise, a `0` base is taken as 10 (decimal), unless the next character is `0`, in which case it is taken as 8 (octal).

The remainder of the string is converted to an unsigned long value in the obvious manner, stopping at the end of the string or at the first character that does not produce a valid digit in the given base. (In bases above 10, the letter `A` in either upper or lower case represents 10, `B` represents 11, and so forth, with `Z` representing 35.)

Return Value

On success, `strtouq()` returns either the result of the conversion or, if there was a leading minus sign, the negation of the result of the conversion, unless the original (non-negated) value would overflow. In the case of an overflow the function returns `UQUAD_MAX` and the global variable `errno` is set to ERANGE.

Errors

ERANGE

The given string was out of range; the value converted has been clamped.

svc_register

Name

`svc_register` — register Remote Procedure Call interface

Synopsis

```
#include <rpc/rpc.h>
bool_t svc_register(SVCXPRT * xprt, rpcprog_t prognum, rpcvers_t versnum,
__dispatch_fn_t dispatch, rpcprot_t protocol);
```

Description

The `svc_register()` function shall associate the program identified by *`prognum`* at version *`versnum`* with the service dispatch procedure, *`dispatch`*. If *`protocol`* is zero, the service is not registered with the `portmap` service. If *`protocol`* is non-zero, then a mapping of the triple [*`prognum`*, *`versnum`*, *`protocol`*] to `xprt->xp_port` is established with the local `portmap` service. The procedure *`dispatch`* has the following form:

```
int dispatch(struct svc_req * request, SVCXPRT * xprt);
```

Return Value

`svc_register()` returns 1 if it succeeds, and zero otherwise.

svc_run

Name

`svc_run` — waits for RPC requests to arrive and calls service procedure

Synopsis

```
#include <rpc/svc.h>
void svc_run(void);
```

Description

The `svc_run()` function shall wait for RPC requests to arrive, read and unpack each request, and dispatch it to the appropriate registered handler. Under normal conditions, `svc_run()` shall not return; it shall only return if serious errors occur that prevent further processing.

svc_sendreply

Name

`svc_sendreply` — called by RPC service's dispatch routine

Synopsis

```
bool_t svc_sendreply(SVCXPRT *xprt, xdrproc_t outproc, caddr_t out);
```

Description

Called by an RPC service's dispatch routine to send the results of a remote procedure call. The parameter *`xprt`* is the request's associated transport handle; *`outproc`* is the XDR routine which is used to encode the results; and *`out`* is the address of the results. This routine returns one if it succeeds, zero other-wise.

svctcp_create

Name

`svctcp_create` — create a TCP/IP-based RPC service transport

Synopsis

```
#include <rpc/rpc.h>
SVCXPRT * svctcp_create(int sock, u_int send_buf_size, u_int recv_buf_size);
```

Description

`svctcp_create()` cretes a TCP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the socket *`sock`*, which may be `RPC_ANYSOCK`, in which case a new socket is created. If the socket is not bound to a local TCP port, then this routine binds it to an arbitrary port. Upon completion, `xprt->xp_sock` is the transport's socket descriptor, and `xprt->xp_port` is the transport's port number. Since TCP-based RPC uses buffered I/O, users may specify the size of buffers; values of zero choose suitable defaults.

Return Value

`svctcp_create()` returns NULL if it fails, or a pointer to the RPC service transport otherwise.

svcudp_create

Name

`svcudp_create` — create a UDP-based RPC service transport

Synopsis

```
SVCXPRT *
svcudp_create(int sock);
```

Description

This call is equivalent to `svcudp_bufcreate(` *`sock`*`,` *`sz`*`,` *`sz`*`)` for some default size SZ.

swscanf

Name

swscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

system

Name

`system` — execute a shell command

Synopsis

```
#include <stdlib.h>
int system(const char * string);
```

Description

The `system()` function shall behave as described in ISO POSIX (2003).

Notes

The fact that `system()` ignores interrupts is often not what a program wants. ISO POSIX (2003) describes some of the consequences; an additional consequence is that a program calling `system()` from a loop cannot be reliably interrupted. Many programs will want to use the `exec()` family of functions instead.

Do not use `system()` from a program with `suid` or `sgid` privileges, because unexpected values for some environment variables might be used to subvert system integrity. Use the `exec()` family of functions instead, but not `execlp()` or `execvp()`. `system()` will not, in fact, work properly from programs with `suid` or `sgid` privileges on systems on which `/bin/sh` is **bash** version 2, since **bash** 2 drops privileges on startup. (Debian uses a modified **bash** which does not do this when invoked as **sh**.)

The check for the availability of `/bin/sh` is not actually performed; it is always assumed to be available. ISO C (1999) specifies the check, but ISO POSIX (2003) specifies that the return shall always be nonzero, since a system without the shell is not conforming, and it is this that is implemented.

It is possible for the shell command to return 127, so that code is not a sure indication that the `execve()` call failed; check the global variable `errno` to make sure.

textdomain

Name

`textdomain` — set the current default message domain

Synopsis

```
#include <libintl.h>
char * textdomain(const char * domainname);
```

Description

The `textdomain()` function shall set the current default message domain to *`domainname`*. Subsequent calls to `gettext()` and `ngettext()` use the default message domain.

If *`domainname`* is NULL, the default message domain shall not be altered.

If *`domainname`* is "", `textdomain()` shall reset the default domain to the system default of "messages".

Return

On success, `textdomain()` shall return the currently selected domain. Otherwise, a null pointer shall be returned, and `errno` is set to indicate the error.

Errors

`ENOMEM`

Insufficent memory available.

unlink

Name

`unlink` — remove a directory entry

Synopsis

```
int unlink(const char * path);
```

Description

`unlink()` is as specified in ISO POSIX (2003), but with differences as listed below.

See also Section 18.1, Additional behaviors: unlink/link on directory.

May return EISDIR on directories

If *`path`* specifies a directory, the implementation may return EISDIR instead of EPERM as specified by ISO POSIX (2003).

Rationale: The Linux kernel has deliberately chosen EISDIR for this case and does not expect to change.

uselocale

Name

`uselocale` — ~~Set~~set locale for thread

Synopsis

```
#include <locale.h>
locale_t uselocale(locale_t newloc);
```

Description

The `uselocale()` function shall set the locale for the calling thread to the locale specified by *`newloc`*.

If *`newloc`* is the value `LC_GLOBAL_LOCALE`, the thread's locale shall be set to the process current global locale, as set by `setlocale()`. If *`newloc`* is `NULL`, the thread's locale is not altered.

Return Value

The `uselocale()` function shall return the previous locale, or `LC_GLOBAL_LOCALE` if the thread local locale has not been previously set.

Errors

None defined.

See Also

`setlocale()`, `freelocale()`, `duplocale()`, `newlocale()`

utmpname

Name

utmpname — set user accounting database

Synopsis

```
#include <utmp.h>
int utmpname(const char * dbname);
```

Description

The utmpname() function shall cause the user accounting database used by the getutent(), getutent_r(), getutxent(), getutxid(), getutxline(), and pututxline() functions to be that named by *dbname*, instead of the system default database. See Section 16.3 for further information.

> **Note:** The LSB does not specify the format of the user accounting database, nor the names of the file or files that may contain it.

Return Value

None.

Errors

None defined.

vasprintf

Name

vasprintf — write formatted output to a dynamically allocated string

Synopsis

```
#include <stdarg.h>
#include <stdio.h>
int vasprintf(char * * restrict ptr, const char * restrict format, va_list
arg);
```

Description

The vasprintf() function shall write formatted output to a dynamically allocated string, and store the address of that string in the location referenced by *ptr*. It shall behave as asprintf(), except that instead of being called with a variable number of arguments, it is called with an argument list as defined by <stdarg.h>.

Return Value

Refer to fprintf().

Errors

Refer to fprintf().

vdprintf

Name

`vdprintf` — write formatted output to a file descriptor

Synopsis

```
#include <stdio.h>
int vdprintf(int fd, const char * restrict format, va_list arg);
```

Description

The `vdprintf()` function shall behave as `vfprintf()`, except that `vdprintf()` shall write output to the ~~first argument is a~~file associated with the file descriptor specified by the *`fd`* argument, rather than place output on a stream (as defined by ISO POSIX (2003)).

Return Value

Refer to `fprintf()`.

Errors

Refer to `fprintf()`.

verrx

Name

`verrx` — display formatted error message and exit

Synopsis

```
#include <stdarg.h>
#include <err.h>
void verrx(int eval, const char * fmt, va_list args);
```

Description

The `verrx()` shall behave as `errx()` except that instead of being called with a variable number of arguments, it is called with an argument list as defined by `<stdarg.h>`.

`verrx()` does not return, but exits with the value of *`eval`*.

Return Value

None.

Errors

None.

vfscanf

Name

vfscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

vfwscanf

Name

vfwscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

vscanf

Name

vscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

vsscanf

Name

vsscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

vswscanf

Name

vswscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

vsyslog

Name

vsyslog — log to system log

Synopsis

```
#include <stdarg.h>
#include <syslog.h>
void vsyslog(int priority, char * message, va_list arglist);
```

Description

The vsyslog() function is identical to syslog() as specified in ISO POSIX (2003), except that *arglist* (as defined by stdarg.h) replaces the variable number of arguments.

vwscanf

Name

vwscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

wait4

Name

wait4 — wait for process termination, BSD style

Synopsis

```
#include <sys/types.h>
#include <sys/resource.h>
```

```
#include <sys/wait.h>
pid_t wait4(pid_t pid, int * status, int options, struct rusage * rusage);
```

Description

`wait4()` suspends execution of the current process until a child (as specified by *`pid`*) has exited, or until a signal is delivered whose action is to terminate the current process or to call a signal handling function. If a child (as requested by *`pid`*) has already exited by the time of the call (a so-called "zombie" process), the function returns immediately. Any system resources used by the child are freed.

The value of *`pid`* can be one of:

< -1

: wait for any child process whose process group ID is equal to the absolute value of *`pid`*.

-1

: wait for any child process; this is equivalent to calling `wait3()`.

0

: wait for any child process whose process group ID is equal to that of the calling process.

> 0

: wait for the child whose process ID is equal to the value of *`pid`*.

The value of options is a bitwise or of zero or more of the following constants:

WNOHANG

: return immediately if no child is there to be waited for.

WUNTRACED

: return for children that are stopped, and whose status has not been reported.

If status is not NULL, `wait4()` stores status information in the location *`status`*. This status can be evaluated with the following macros:

> **Note:** These macros take the `status` value (an `int`) as an argument -- not a pointer to the value!

WIFEXITED(status)

: is nonzero if the child exited normally.

WEXITSTATUS(status)

: evaluates to the least significant eight bits of the return code of the child that terminated, which may have been set as the argument to a call to `exit()` or as the argument for a return statement in the main program. This macro can only be evaluated if `WIFEXITED()` returned nonzero.

WIFSIGNALED(status)

: returns true if the child process exited because of a signal that was not caught.

WTERMSIG(status)

returns the number of the signal that caused the child process to terminate. This macro can only be evaluated if `WIFSIGNALED()` returned nonzero.

WIFSTOPPED(status)

returns true if the child process that caused the return is currently stopped; this is only possible if the call was done using `WUNTRACED()`.

WSTOPSIG(status)

returns the number of the signal that caused the child to stop. This macro can only be evaluated if `WIFSTOPPED()` returned nonzero.

If *`rusage`* is not NULL, the struct `rusage` (as defined in `sys/resource.h`) that it points to will be filled with accounting information. See `getrusage()` for details.

Return Value

On success, the process ID of the child that exited is returned. On error, -1 is returned (in particular, when no unwaited-for child processes of the specified kind exist), or 0 if `WNOHANG()` was used and no child was available yet. In the latter two cases, the global variable `errno` is set appropriately.

Errors

ECHILD

No unwaited-for child process as specified does exist.

ERESTARTSYS

A `WNOHANG()` was not set and an unblocked signal or a `SIGCHILD` was caught. This error is returned by the system call. The library interface is not allowed to return ERESTARTSYS, but will return EINTR.

waitpid

Name

`waitpid` — wait for child process

Description

`waitpid()` is as specified in ISO POSIX (2003), but with differences as listed below.

Need not support `WCONTINUED` or `WIFCONTINUED`

Implementations need not support the XSI optional functionality of `WCONTINUED()` or `WIFCONTINUED()`.

warn

Name

warn — formatted error messages

Synopsis

```
#include <err.h>
void warn(const char * fmt, ...);
```

Description

The warn() function shall display a formatted error message on the standard error stream. The output shall consist of the last component of the program name, a colon character, and a space character. If *fmt* is non-NULL, it shall be used as a format string for the printf() family of functions, and the formatted message, a colon character, and a space are written to stderr. Finally, the error message string affiliated with the current value of the global variable errno shall be written to stderr, followed by a newline character.

Return Value

None.

Errors

None.

warnx

Name

warnx — formatted error messages

Synopsis

```
#include <err.h>
void warnx(const char * fmt, ...);
```

Description

The warnx() function shall display a formatted error message on the standard error stream. The last component of the program name, a colon character, and a space shall be output. If *fmt* is non-NULL, it shall be used as the format string for the printf() family of functions, and the formatted error message, a colon character, and a space shall be output. The output shall be followed by a newline character.

Return Value

None.

Errors

None.

wcpcpy

Name

wcpcpy — copy a wide character string, returning a pointer to its end

Synopsis

```
#include <wchar.h>
wchar_t * wcpcpy(wchar_t * dest, const wchar_t * src);
```

Description

wcpcpy() is the wide-character equivalent of stpcpy(). It copies the wide character string *src*, including the terminating null wide character code, to the array *dest*.

The strings may not overlap.

The programmer shall ensure that there is room for at least wcslen()*(src)*+1 wide characters at *dest*.

Return Value

wcpcpy() returns a pointer to the end of the wide-character string *dest*, that is, a pointer to the terminating null wide character code.

wcpncpy

Name

wcpncpy — copy a fixed-size string of wide characters, returning a pointer to its end

Synopsis

```
#include <wchar.h>
wchar_t * wcpncpy(wchar_t * dest, const wchar_t * src, size_t n);
```

Description

wcpncpy() is the wide-character equivalent of stpncpy(). It copies at most *n* wide characters from the wide-character string *src*, including the terminating null wide character code, to the array *dest*. Exactly *n* wide characters are written at *dest*. If the length wcslen()*(src)* is smaller than *n*, the remaining wide characters in the array *dest* are filled with null wide character codes. If the length wcslen()*(src)* is greater than or equal to *n*, the string *dest* will not be terminated with a null wide character code.

The strings may not overlap.

The programmer shall ensure that there is room for at least *n* wide characters at *dest*.

Return Value

wcpncpy() returns a pointer to the wide character one past the last non-null wide character written.

wcscasecmp

Name

wcscasecmp — compare two wide-character strings, ignoring case

Synopsis

```
#include <wchar.h>
int wcscasecmp(const wchar_t * s1, const wchar_t * s2);
```

Description

wcscasecmp() is the wide-character equivalent of strcasecmp(). It compares the wide-character string *s1* and the wide-character string *s2*, ignoring case differences (towupper, towlower).

Return Value

The wcscasecmp() function shall return 0 if the wide-character strings *s1* and *s2* are equal except for case distinctions. It shall return a positive integer if *s1* is greater than *s2*, ignoring case. It shall return a negative integer if *s1* is less than *s2*, ignoring case.

Notes

The behavior of wcscasecmp() depends upon the LC_CTYPE category of the current locale.

wcsdup

Name

wcsdup — duplicate a wide-character string

Synopsis

```
#include <wchar.h>
wchar_t * wcsdup(const wchar_t * s);
```

Description

wcsdup() is the wide-character equivalent of strdup(). It allocates and returns a new wide-character string whose initial contents is a duplicate of the wide-character string *s*.

Memory for the new wide-character string is obtained with malloc(), and can be freed with free().

Return Value

wcsdup() returns a pointer to the new wide-character string, or NULL if sufficient memory was not available.

wcsncasecmp

Name

wcsncasecmp — compare two fixed-size wide-character strings, ignoring case

Synopsis

```
#include <wchar.h>
int wcsncasecmp(const wchar_t * s1, const wchar_t * s2, size_t n);
```

Description

wcsncasecmp() is the wide-character equivalent of strncasecmp(). It compares the wide-character string *s1* and the wide-character string *s2*, but at most *n* wide characters from each string, ignoring case differences (towupper, towlower).

Return Value

wcscasecmp() returns 0 if the wide-character strings *s1* and *s2*, truncated to at most length *n*, are equal except for case distinctions. It returns a positive integer if truncated *s1* is greater than truncated *s2*, ignoring case. It returns a negative integer if truncated *s1* is smaller than truncated *s2*, ignoring case.

Notes

The behavior of wcsncasecmp() depends upon the LC_CTYPE category of the current locale.

wcsnlen

Name

wcsnlen — determine the length of a fixed-size wide-character string

Synopsis

```
#include <wchar.h>
size_t wcsnlen(const wchar_t * s, size_t maxlen);
```

Description

wcsnlen() is the wide-character equivalent of strnlen(). It returns the number of wide-characters in the string *s*, not including the terminating null wide character code, but at most *maxlen*. In doing this, wcsnlen() looks only at the first *maxlen* wide-characters at *s* and never beyond *s* + *maxlen*.

Return Value

wcsnlen() returns wcslen()*(s)* if that is less than *maxlen*, or *maxlen* if there is no null wide character code among the first *maxlen* wide characters pointed to by *s*.

wcsnrtombs

Name

wcsnrtombs — convert a wide character string to a multi-byte string

Synopsis

```
#include <wchar.h>
size_t wcsnrtombs(char * dest, const wchar_t * * src, size_t nwc, size_t len,
mbstate_t * ps);
```

Description

wcsnrtombs() is like wcsrtombs(), except that the number of wide characters to be converted, starting at *src*, is limited to *nwc*.

If *dest* is not a NULL pointer, wcsnrtombs() converts at most *nwc* wide characters from the wide-character string *src* to a multibyte string starting at *dest*. At most *len* bytes are written to *dest*. The state *ps* is updated.

The conversion is effectively performed by repeatedly calling:

```
wcrtomb(dest, *src, ps)
```

as long as this call succeeds, and then incrementing *dest* by the number of bytes written and *src* by 1.

The conversion can stop for three reasons:

- A wide character has been encountered that cannot be represented as a multibyte sequence (according to the current locale). In this case *src* is left pointing to the invalid wide character, (size_t)(-1) is returned, and errno is set to EILSEQ.
- *nws* wide characters have been converted without encountering a null wide character code, or the length limit forces a stop. In this case, *src* is left pointing to the next wide character to be converted, and the number bytes written to *dest* is returned.
- The wide-character string has been completely converted, including the terminating null wide character code (which has the side effect of bringing back *ps* to the initial state). In this case, *src* is set to NULL, and the number of bytes written to *dest*, excluding the terminating null wide character code, is returned.

If *dest* is NULL, *len* is ignored, and the conversion proceeds as above, except that the converted bytes are not written out to memory, and that no destination length limit exists.

In both of the above cases, if *ps* is a NULL pointer, a static anonymous state only known to wcsnrtombs() is used instead.

The programmer shall ensure that there is room for at least *len* bytes at *dest*.

Return Value

wcsnrtombs() returns the number of bytes that make up the converted part of multibyte sequence, not including the terminating null wide character code. If a wide character was encountered which could not be converted, (size_t)(-1) is returned, and the global variable errno set to EILSEQ.

Notes

The behavior of wcsnrtombs() depends on the LC_CTYPE category of the current locale.

Passing NULL as *ps* is not multi-thread safe.

wcstoq

Name

wcstoq — convert wide string to long long int representation

Synopsis

```
#include <wchar.h>
long long int wcstoq(const wchar_t * restrict nptr, wchar_t ** restrict
endptr, int base);
```

Description

The wcstoq() function shall convert the initial portion of the wide string *nptr* to long long int representation. It is identical to wcstoll().

Return Value

Refer to wcstoll().

Errors

Refer to wcstoll().

wcstouq

Name

wcstouq — convert wide string to unsigned long long int representation

Synopsis

```
#include <wchar.h>
unsigned long long wcstouq(const wchar_t * restrict nptr, wchar_t **
restrict endptr, int base);
```

Description

The wcstouq() function shall convert the initial portion of the wide string *nptr* to unsigned long long int representation. It is identical to wcstoull().

Return Value

Refer to wcstoull().

Errors

Refer to wcstoull().

wscanf

Name

wscanf — convert formatted input

Description

The scanf() family of functions shall behave as described in ISO POSIX (2003), except as noted below.

Differences

The %s, %S and %[conversion specifiers shall accept an option length modifier a, which shall cause a memory buffer to be allocated to hold the string converted. In such a case, the argument corresponding to the conversion specifier should be a reference to a pointer value that will receive a pointer to the allocated buffer. If there is insufficient memory to allocate a buffer, the function may set errno to ENOMEM and a conversion error results.

> **Note:** This directly conflicts with the ISO C (1999) usage of %a as a conversion specifier for hexadecimal float values. While this conversion specifier should be supported, a format specifier such as "%aseconds" will have a different meaning on an LSB conforming system.

xdr_u_int

Name

xdr_u_int — library routines for external data representation

Synopsis

```
int xdr_u_int(XDR * xdrs, unsigned int * up);
```

Description

xdr_u_int() is a filter primitive that translates between C unsigned integers and their external representations.

Return Value

On success, 1 is returned. On error, 0 is returned.

13.6 Interfaces for libm

Table 13-24 defines the library name and shared object name for the libm library

Table 13-24 libm Definition

Library:	libm
SONAME:	See archLSB.

The behavior of the interfaces in this library is specified by the following specifications:

[ISOC99] ISO C (1999)
[LSB] ~~this specification~~This Specification

[SUSv2] SUSv2
[SUSv3] ISO POSIX (2003)

13.6.1 Math

13.6.1.1 Interfaces for Math

An LSB conforming implementation shall provide the generic functions for Math specified in Table 13-25, with the full mandatory functionality as described in the referenced underlying specification.

Table 13-25 libm - Math Function Interfaces

~~__finite [1]~~	~~ccosl [2]~~	~~exp [2]~~	~~j1l [1]~~	~~powf [2]~~

13.7 Data Definitions for libm

This section defines global identifiers and their values that are associated with interfaces contained in libm. These definitions are organized into groups that correspond to system headers. This convention is used as a convenience for the reader, and does not imply the existence of these headers, or their content.

~~These definitions are intended to supplement those provided in~~ Where an interface is defined as requiring a particular system header file all of the ~~referenced underlying~~data definitions for that system header file presented here shall be in effect.

This section gives data definitions to promote binary application portability, not to repeat source interface definitions available elsewhere. System providers and application developers should use this ABI to supplement - not to replace - source interface definition specifications.

This specification uses ~~ISO/IEC 9899~~the ISO C (1999) C Language as the reference programming language, and data definitions are specified in ISO C format. The C language is used here as a convenient notation. Using a C language description of these data objects does not preclude their use by other programming languages.

13.8 Interface Definitions for libm

The ~~following~~ interfaces defined on the following pages are included in libm and are defined by this specification. Unless otherwise noted, these interfaces shall be included in the source standard.

Other interfaces listed ~~above for libm~~in Section 13.6 shall behave as described in the referenced base document.

__fpclassify

Name

__fpclassify — Classify real floating type

Synopsis

```
int __fpclassify(double arg);
```

Description

__fpclassify() has the same specification as fpclassify() in ISO POSIX (2003), except that the argument type for __fpclassify() is known to be double.

__fpclassify() is not in the source standard; it is only in the binary standard.

__fpclassifyf

Name

__fpclassifyf — Classify real floating type

Synopsis

```
int __fpclassifyf(float arg);
```

Description

__fpclassifyf() has the same specification as fpclassifyf() in ISO POSIX (2003), except that the argument type for __fpclassifyf() is known to be float.

__fpclassifyf() is not in the source standard; it is only in the binary standard.

13.9 Interfaces for libpthread

Table 13-27 defines the library name and shared object name for the libpthread library

Table 13-27 libpthread Definition

Library:	libpthread
SONAME:	libpthread.so.0

The behavior of the interfaces in this library is specified by the following specifications:

[LFS] Large File Support
[LSB] ~~this specification~~This Specification
[SUSv3] ISO POSIX (2003)

13.9.1 Realtime Threads

13.9.1.1 Interfaces for Realtime Threads

An LSB conforming implementation shall provide the generic functions for Realtime Threads specified in Table 13-28, with the full mandatory functionality as described in the referenced underlying specification.

6380 **Table 13-28 libpthread - Realtime Threads Function Interfaces**

~~pthread_attr_getinheritsched [1]~~	~~pthread_attr_getscope [1]~~	~~pthread_attr_setschedpolicy [1]~~	~~pthread_getschedparam [1]~~	~~pthread_setschedprio(GLIBC_2.3.4) [1]~~
~~pthread_attr_getschedpolicy [1]~~	~~pthread_attr_setinheritsched [1]~~	~~pthread_attr_setscope [1]~~	~~pthread_setschedparam [1]~~

13.10 Data Definitions for libpthread

This section defines global identifiers and their values that are associated with interfaces contained in libpthread. These definitions are organized into groups that correspond to system headers. This convention is used as a convenience for the reader, and does not imply the existence of these headers, or their content.

~~These definitions are intended to supplement those provided in~~ Where an interface is defined as requiring a particular system header file all of the ~~referenced underlying~~data definitions for that system header file presented here shall be in effect.

This section gives data definitions to promote binary application portability, not to repeat source interface definitions available elsewhere. System providers and application developers should use this ABI to supplement - not to replace - source interface definition specifications.

This specification uses ~~ISO/IEC 9899~~the ISO C (1999) C Language as the reference programming language, and data definitions are specified in ISO C format. The C language is used here as a convenient notation. Using a C language description of these data objects does not preclude their use by other programming languages.

13.10.1 pthread.h

```
#define PTHREAD_SCOPE_SYSTEM    0
#define PTHREAD_MUTEX_DEFAULT   1
#define PTHREAD_MUTEX_NORMAL    1

```

13.11 Interface Definitions for libpthread

The ~~following~~ interfaces defined on the following pages are included in libpthread and are defined by this specification. Unless otherwise noted, these interfaces shall be included in the source standard.

Other interfaces listed ~~above for libpthread~~in Section 13.9 shall behave as described in the referenced base document.

_pthread_cleanup_pop

Name

_pthread_cleanup_pop — establish cancellation handlers

Synopsis

```
#include <pthread.h>
void _pthread_cleanup_pop(struct _pthread_cleanup_buffer *, int);
```

Description

The _pthread_cleanup_pop() function provides an implementation of the pthread_cleanup_pop() macro described in *ISO POSIX (2003)*.

The _pthread_cleanup_pop() function is not in the source standard; it is only in the binary standard.

_pthread_cleanup_push

Name

_pthread_cleanup_push — establish cancellation handlers

Synopsis

```
#include <pthread.h>
void _pthread_cleanup_push(struct _pthread_cleanup_buffer *, void (*)
(void *), void *);
```

Description

The _pthread_cleanup_push() function provides an implementation of the pthread_cleanup_push() macro described in *ISO POSIX (2003)*.

The _pthread_cleanup_push() function is not in the source standard; it is only in the binary standard.

13.12 Interfaces for libgcc_s

Table 13-31 defines the library name and shared object name for the libgcc_s library

Table 13-31 libgcc_s Definition

Library:	libgcc_s
SONAME:	libgcc_s.so.1

13.12.1 Unwind Library

13.12.1.1 Interfaces for Unwind Library

No external functions are defined for libgcc_s - Unwind Library in this part of the specification. See also the relevant architecture specific supplement.

13.13 Data Definitions for libgcc_s

This section defines global identifiers and their values that are associated with interfaces contained in libgcc_s. These definitions are organized into groups that correspond to system headers. This convention is used as a convenience for the reader, and does not imply the existence of these headers, or their content.

~~These definitions are intended to supplement those provided in~~ Where an interface is defined as requiring a particular system header file all of the ~~referenced underlying~~data definitions for that system header file presented here shall be in effect.

This section gives data definitions to promote binary application portability, not to repeat source interface definitions available elsewhere. System providers and application developers should use this ABI to supplement - not to replace - source interface definition specifications.

This specification uses ~~ISO/IEC 9899~~the ISO C (1999) C Language as the reference programming language, and data definitions are specified in ISO C format. The C language is used here as a convenient notation. Using a C language description of these data objects does not preclude their use by other programming languages.

13.13.1 unwind.h

```

dlsym [LSB]			

13.15 Data Definitions for libdl

This section defines global identifiers and their values that are associated with interfaces contained in libdl. These definitions are organized into groups that correspond to system headers. This convention is used as a convenience for the reader, and does not imply the existence of these headers, or their content.

~~These definitions are intended to supplement those provided in~~ Where an interface is defined as requiring a particular system header file all of the ~~referenced underlying~~data definitions for that system header file presented here shall be in effect.

This section gives data definitions to promote binary application portability, not to repeat source interface definitions available elsewhere. System providers and application developers should use this ABI to supplement - not to replace - source interface definition specifications.

This specification uses ~~ISO/IEC 9899~~the ISO C (1999) C Language as the reference programming language, and data definitions are specified in ISO C format. The C language is used here as a convenient notation. Using a C language description of these data objects does not preclude their use by other programming languages.

13.15.1 dlfcn.h

```
#define RTLD_NEXT       ((void *) -1l)
#define RTLD_LOCAL      0
#define RTLD_LAZY       0x00001
#define RTLD_NOW        0x00002
#define RTLD_GLOBAL     0x00100

typedef struct {
{
    char *dli_fname;
    void *dli_fbase;
```

```
7111            char *dli_sname;
7112            void *dli_saddr;
7113        }
7114         Dl_info;
7115        extern int dladdr(const void *, Dl_info *);
7116        extern int dlclose(void *);
7117        extern char *dlerror(void);
7118        extern void *dlopen(char *, int);
7119        extern void *dlsym(void *, char *);
```

13.16 Interface Definitions for libdl

7120 The ~~following~~ interfaces defined on the following pages are included in libdl and are
7121 defined by this specification. Unless otherwise noted, these interfaces shall be
7122 included in the source standard.

7123 Other interfaces listed ~~above for libdl~~in Section 13.14 shall behave as described in the
7124 referenced base document.

dladdr

Name

7125 `dladdr` — find the shared object containing a given address

Synopsis

```
7126 #include <dlfcn.h>
7127
7128 typedef struct {
7129             const char  *dli_fname;
7130             void        *dli_fbase;
7131             const char  *dli_sname;
7132             void        *dli_saddr;
```

```
} Dl_info;

int dladdr(const void * addr, Dl_info * dlip);
```

Description

The `dladdr()` function shall query the dynamic linker for information about the shared object containing the address *`addr`*. The information shall be returned in the user supplied data structure referenced by *`dlip`*.

The structure shall contain at least the following members:

`dli_fname`

The pathname of the shared object containing the address

`dli_fbase`

The base address at which the shared object is mapped into the address space of the calling process.

`dli_sname`

The name of the nearest runtime symbol with value less than or equal to *`addr`*. Where possible, the symbol name shall be returned as it would appear in C source code.

If no symbol with a suitable value is found, both this field and *`dli_saddr`* shall be set to `NULL`.

`dli_saddr`

The address of the symbol returned in *`dli_sname`*. This address has type "pointer to *`type`*", where *`type`* is the type of the symbol *`dli_sname`*.

Example: If the symbol in *`dli_sname`* is a function, then the type of *`dli_saddr`* is of type "pointer to function".

The behavior of `dladdr()` is only specified in dynamically linked programs.

Return Value

On success, `dladdr()` shall return non-zero, and the structure referenced by *`dlip`* shall be filled in as described. Otherwise, `dladdr()` shall return zero, and the cause of the error can be fetched with `dlerror()`.

Errors

See `dlerror()`.

Environment

`LD_LIBRARY_PATH`

directory search-path for object files

dlopen

Name

dlopen — open dynamic object

Synopsis

```
#include <dlfcn.h>

void * dlopen(const char * filename, int flag);
```

Description

The dlopen() function shall behave as specified in ISO POSIX (2003), but with additional behaviors listed below.

If the file argument does not contain a slash character, then the system shall look for a library of that name in at least the following directories, and use the first one which is found:

- The directories specified by the DT_RPATH dynamic entry.
- The directories specified in the LD_LIBRARY_PATH environment variable (which is a colon separated list of pathnames). This step shall be skipped for setuid and setgid executables.
- A set of directories sufficient to contain the libraries specified in this standard.

  Note: Traditionally, /lib and /usr/lib. This case would also cover cases in which the system used the mechanism of /etc/ld.so.conf and /etc/ld.so.cache to provide access.

  Example: An application which is not linked against libm may choose to dlopen libm.

dlsym

Name

dlsym — obtain the address of a symbol from a dlopen object

Description

dlsym() is as specified in the ISO POSIX (2003), but with differences as listed below.

The special purpose value for handle RTLD_NEXT

The value RTLD_NEXT, which is reserved for future use shall be available, with the behavior as described in ISO POSIX (2003).

13.17 Interfaces for librt

Table 13-34 defines the library name and shared object name for the librt library

Table 13-34 librt Definition

Library:	librt
SONAME:	librt.so.1

The behavior of the interfaces in this library is specified by the following specifications:

[SUSv3] ISO POSIX (2003)

13.17.1 Shared Memory Objects

13.17.1.1 Interfaces for Shared Memory Objects

An LSB conforming implementation shall provide the generic functions for Shared Memory Objects specified in Table 13-35, with the full mandatory functionality as described in the referenced underlying specification.

13.19 Interfaces for libpam

Table 13-40 defines the library name and shared object name for the libpam library

Table 13-40 libpam Definition

Library:	libpam
SONAME:	libpam.so.0

The Pluggable Authentication Module (PAM) interfaces allow applications to request authentication via a system administrator defined mechanism, known as a *service*.

A single service name, `other`, shall always be present. The behavior of this service shall be determined by the system administrator. Additional service names may also exist. [1]

1 **Note:** Future versions of this specification might define additional service names.

The behavior of the interfaces in this library is specified by the following specifications:

[LSB] this specificationThis Specification

13.19.1 Pluggable Authentication API

13.19.1.1 Interfaces for Pluggable Authentication API

An LSB conforming implementation shall provide the generic functions for Pluggable Authentication API specified in Table 13-41, with the full mandatory functionality as described in the referenced underlying specification.

Table 13-41 libpam - Pluggable Authentication API Function Interfaces

```

13.21 Interface Definitions for libpam

The ~~following~~ interfaces defined on the following pages are included in libpam and are defined by this specification. Unless otherwise noted, these interfaces shall be included in the source standard.

Other interfaces listed ~~above for libpam~~in Section 13.19 shall behave as described in the referenced base document.

pam_acct_mgmt

Name

`pam_acct_mgmt` — establish the status of a user's account

Synopsis

```
#include <security/pam_appl.h>
int pam_acct_mgmt(pam_handle_t * pamh, int flags);
```

Description

`pam_acct_mgmt()` establishes the account's usability and the user's accessibility to the system. It is typically called after the user has been authenticated.

`flags` may be specified as any valid flag (namely, one of those applicable to the *`flags`* argument of `pam_authenticate()`). Additionally, the value of *`flags`* may be logically or'd with `PAM_SILENT`.

Return Value

PAM_SUCCESS

Success.

PAM_NEW_AUTHTOK_REQD

User is valid, but user's authentication token has expired. The correct response to this return-value is to require that the user satisfy the `pam_chauthtok()` function before obtaining service. It may not be possible for an application to do this. In such a case, the user should be denied access until the account password is updated.

PAM_ACCT_EXPIRED

User is no longer permitted access to the system.

PAM_AUTH_ERR

Authentication error.

PAM_PERM_DENIED

User is not permitted to gain access at this time.

PAM_USER_UNKNOWN

User is not known to a module's account management component.

Note: Errors may be translated to text with `pam_strerror()`.

pam_authenticate

Name

`pam_authenticate` — authenticate the user

Synopsis

```
#include <security/pam_appl.h>
int pam_authenticate(pam_handle_t * pamh, int flags);
```

Description

`pam_authenticate()` serves as an interface to the authentication mechanisms of the loaded modules.

`flags` is an optional parameter that may be specified by the following value:

PAM_DISALLOW_NULL_AUTHTOK

Instruct the authentication modules to return `PAM_AUTH_ERR` if the user does not have a registered authorization token.

Additionally, the value of *`flags`* may be logically or'd with `PAM_SILENT`.

The process may need to be privileged in order to successfully call this function.

Return Value

PAM_SUCCESS

Success.

PAM_AUTH_ERR

User was not authenticated or process did not have sufficient privileges to perform authentication.

PAM_CRED_INSUFFICIENT

Application does not have sufficient credentials to authenticate the user.

PAM_AUTHINFO_UNAVAIL

Modules were not able to access the authentication information. This might be due to a network or hardware failure, etc.

PAM_USER_UNKNOWN

Supplied username is not known to the authentication service.

PAM_MAXTRIES

One or more authentication modules has reached its limit of tries authenticating the user. Do not try again.

PAM_ABORT

One or more authentication modules failed to load.

Note: Errors may be translated to text with `pam_strerror()`.

pam_chauthtok

Name

`pam_chauthtok` — change the authentication token for a given user

Synopsis

```
#include <security/pam_appl.h>
int pam_chauthtok(pam_handle_t * pamh, const int flags);
```

Description

`pam_chauthtok()` is used to change the authentication token for a given user as indicated by the state associated with the handle *`pamh`*.

`flags` is an optional parameter that may be specified by the following value:

PAM_CHANGE_EXPIRED_AUTHTOK

User's authentication token should only be changed if it has expired.

Additionally, the value of *`flags`* may be logically or'd with `PAM_SILENT`.

RETURN VALUE

PAM_SUCCESS

Success.

PAM_AUTHTOK_ERR

A module was unable to obtain the new authentication token.

PAM_AUTHTOK_RECOVER_ERR

A module was unable to obtain the old authentication token.

PAM_AUTHTOK_LOCK_BUSY

One or more modules were unable to change the authentication token since it is currently locked.

PAM_AUTHTOK_DISABLE_AGING

Authentication token aging has been disabled for at least one of the modules.

PAM_PERM_DENIED

Permission denied.

PAM_TRY_AGAIN

Not all modules were in a position to update the authentication token(s). In such a case, none of the user's authentication tokens are updated.

PAM_USER_UNKNOWN

User is not known to the authentication token changing service.

Note: Errors may be translated to text with `pam_strerror()`.

pam_close_session

Name

pam_close_session — indicate that an authenticated session has ended

Synopsis

```
#include <security/pam_appl.h>
int pam_close_session(pam_handle_t * pamh, int flags);
```

Description

pam_close_session() is used to indicate that an authenticated session has ended. It is used to inform the module that the user is exiting a session. It should be possible for the PAM library to open a session and close the same session from different applications.

flags may have the value PAM_SILENT to indicate that no output should be generated as a result of this function call.

Return Value

PAM_SUCCESS

Success.

PAM_SESSION_ERR

One of the required loaded modules was unable to close a session for the user.

Note: Errors may be translated to text with pam_strerror().

pam_end

Name

pam_end — terminate the use of the PAM library

Synopsis

```
#include <security/pam_appl.h>
int pam_end(pam_handle_t * pamh, int pam_status);
```

Description

pam_end() terminates use of the PAM library. On success, the contents of **pamh* are no longer valid, and all memory associated with it is invalid.

Normally, *pam_status* is passed the value PAM_SUCCESS, but in the event of an unsuccessful service application, the appropriate PAM error return value should be used.

Return Value

PAM_SUCCESS

Success.

Note: Errors may be translated to text with pam_strerror().

pam_fail_delay

Name

pam_fail_delay — specify delay time to use on authentication error

Synopsis

```
#include <security/pam_appl.h>
int pam_fail_delay(pam_handle_t * pamh, unsigned int micro_sec);
```

Description

pam_fail_delay() specifies the minimum delay for the PAM library to use when an authentication error occurs. The actual delay can vary by as much at 25%. If this function is called multiple times, the longest time specified by any of the call will be used.

The delay is invoked if an authentication error occurs during the pam_authenticate() or pam_chauthtok() function calls.

Independent of the success of pam_authenticate() or pam_chauthtok(), the delay time is reset to its default value of 0 when the PAM library returns control to the application from these two functions.

Return Value

PAM_SUCCESS

Success.

Note: Errors may be translated to text with pam_strerror().

pam_get_item

Name

pam_get_item — obtain the value of the indicated item.

Synopsis

```
#include <security/pam_appl.h>
int pam_get_item(const pam_handle_t * pamh, int item_type, const void * *
item);
```

Description

pam_get_item() obtains the value of the indicated *item_type*. The possible values of *item_type* are the same as listed for pam_set_item().

On success, *item* contains a pointer to the value of the corresponding item. Note that this is a pointer to the actual data and should not be free()'d or over-written.

Return Value

PAM_SUCCESS

Success.

PAM_PERM_DENIED

Application passed a NULL pointer for item.

PAM_BAD_ITEM

Application attempted to get an undefined item.

Note: Errors may be translated to text with pam_strerror().

pam_getenvlist

Name

pam_getenvlist — returns a pointer to the complete PAM environment.

Synopsis

```
#include <security/pam_appl.h>
char * const * pam_getenvlist(pam_handle_t * pamh);
```

Description

pam_getenvlist() returns a pointer to the complete PAM environment. This pointer points to an array of pointers to NUL-terminated strings and must be terminated by a NULL pointer. Each string has the form "name=value".

The PAM library module allocates memory for the returned value and the associated strings. The calling application is responsible for freeing this memory.

Return Value

pam_getenvlist() returns an array of string pointers containing the PAM environment. On error, NULL is returned.

pam_open_session

Name

`pam_open_session` — indicate session has started

Synopsis

```
#include <security/pam_appl.h>
int pam_open_session(pam_handle_t * pamh, int flags);
```

Description

The `pam_open_session()` function is used to indicate that an authenticated session has begun, after the user has been identified (see `pam_authenticate()`) and, if necessary, granted credentials (see `pam_setcred()`). It is used to inform the module that the user is currently in a session. It should be possible for the PAM library to open a session and close the same session from different applications.

`flags` may have the value `PAM_SILENT` to indicate that no output be generated as a result of this function call.

Return Value

PAM_SUCCESS

Success.

PAM_SESSION_ERR

One of the loaded modules was unable to open a session for the user.

~~ERRORS~~

~~May~~**Note:** Errors may be translated to text with `pam_strerror()`.

pam_set_item

Name

pam_set_item — (re)set the value of an item.

Synopsis

```
#include <security/pam_appl.h>
int pam_set_item(pam_handle_t * pamh, int item_type, const void * item);
```

Description

pam_set_item() (re)sets the value of one of the following item_types:

PAM_SERVICE

service name

PAM_USER

user name

PAM_TTY

terminal name

The value for a device file should include the /dev/ prefix. The value for graphical, X-based, applications should be the $DISPLAY variable.

PAM_RHOST

remote host name

PAM_CONV

conversation structure

PAM_RUSER

remote user name

PAM_USER_PROMPT

string to be used when prompting for a user's name

The default value for this string is Please enter username: .

For all *item_types* other than PAM_CONV, *item* is a pointer to a NULL-terminated character string. In the case of PAM_CONV, *item* points to an initialized pam_conv structure.

Return Value

PAM_SUCCESS

Success.

PAM_PERM_DENIED

An attempt was made to replace the conversation structure with a NULL value.

PAM_BUF_ERR

Function ran out of memory making a copy of the item.

PAM_BAD_ITEM

Application attempted to set an undefined item.

Note: Errors may be translated to text with `pam_strerror()`.

pam_setcred

Name

`pam_setcred` — set the module-specific credentials of the user

Synopsis

```
#include <security/pam_appl.h>
extern int pam_setcred(pam_handle_t * pamh, int flags);
```

Description

`pam_setcred()` sets the module-specific credentials of the user. It is usually called after the user has been authenticated, after the account management function has been called and after a session has been opened for the user.

`flags` maybe specified from among the following values:

PAM_ESTABLISH_CRED

: set credentials for the authentication service

PAM_DELETE_CRED

: delete credentials associated with the authentication service

PAM_REINITIALIZE_CRED

: reinitialize the user credentials

PAM_REFRESH_CRED

: extend lifetime of the user credentials

Additionally, the value of *`flags`* may be logically or'd with `PAM_SILENT`.

Return Value

PAM_SUCCESS

: Success.

PAM_CRED_UNAVAIL

: Module cannot retrieve the user's credentials.

PAM_CRED_EXPIRED

: User's credentials have expired.

PAM_USER_UNKNOWN

: User is not known to an authentication module.

PAM_CRED_ERR

: Module was unable to set the credentials of the user.

Note: Errors may be translated to text with `pam_strerror()`.

pam_start

Name

pam_start — initialize the PAM library

Synopsis

```
#include <security/pam_appl.h>
int pam_start(const char * service_name, const char * user, const struct
pam_conv * pam_conversation, pam_handle_t * * pamh);
```

Description

pam_start() is used to initialize the PAM library. It must be called prior to any other usage of the PAM library. On success, **pamh* becomes a handle that provides continuity for successive calls to the PAM library. pam_start() expects arguments as follows: the *service_name* of the program, the *username* of the individual to be authenticated, a pointer to an application-supplied pam_conv structure, and a pointer to a *pam_handle_t* pointer.

An application must provide the *conversation function* used for direct communication between a loaded module and the application. The application also typically provides a means for the module to prompt the user for a password, etc.

The structure, pam_conv, is defined to be,

```
struct pam_conv {
            int (*conv) (int num_msg,
                         const struct pam_message * *msg,
                         struct pam_response * *resp,
                         void *appdata_ptr);
            void *appdata_ptr;
```

```
};
```

It is initialized by the application before it is passed to the library. The contents of this structure are attached to the **pamh* handle. The point of this argument is to provide a mechanism for any loaded module to interact directly with the application program; this is why it is called a conversation structure.

When a module calls the referenced `conv()` function, *`appdata_ptr`* is set to the second element of this structure.

The other arguments of a call to `conv()` concern the information exchanged by module and application. *`num_msg`* holds the length of the array of pointers passed via *`msg`*. On success, the pointer *`resp`* points to an array of *`num_msg`* `pam_response` structures, holding the application-supplied text. Note that *`resp`* is a struct `pam_response` array and not an array of pointers.

Return Value

PAM_SUCCESS

Success.

PAM_BUF_ERR

Memory allocation error.

PAM_ABORT

Internal failure.

ERRORS

May be translated to text with `pam_strerror()`.

pam_strerror

Name

`pam_strerror` — returns a string describing the PAM error

Synopsis

```
#include <security/pam_appl.h>
const char * pam_strerror(pam_handle_t * pamh, int errnum);
```

Description

`pam_strerror()` returns a string describing the PAM error associated with *`errnum`*.

Return Value

On success, this function returns a description of the indicated error. The application should not free or modify this string. Otherwise, a string indicating that the error is unknown shall be returned. It is unspecified whether or not the string returned is translated according to the setting of LC_MESSAGES.

IV Utility Libraries

14 Utility Libraries

14.1 Introduction

An LSB-conforming implementation shall also support the following utility libraries which are built on top of the interfaces provided by the base libraries. These libraries implement common functionality, and hide additional system dependent information such as file formats and device names.

- libz
- libcurses
- libutil

The structure of the definitions for these libraries follows the same model as used for Base Libraries.

14.2 Interfaces for libz

Table 14-1 defines the library name and shared object name for the libz library

Table 14-1 libz Definition

Library:	libz
SONAME:	libz.so.1

The behavior of the interfaces in this library is specified by the following specifications:

[LSB] ~~this specification~~This Specification

14.2.1 Compression Library

14.2.1.1 Interfaces for Compression Library

An LSB conforming implementation shall provide the generic functions for Compression Library specified in Table 14-2, with the full mandatory functionality as described in the referenced underlying specification.

Table 14-2 libz - Compression Library Function Interfaces

~~adler32 [1]~~	~~deflateInit2_ [1]~~	~~gzerror [1]~~	~~gzrewind [1]~~	~~inflateReset [1]~~
~~compress [1]~~	~~deflateInit_ [1]~~	~~gzflush [1]~~	~~gzseek [1]~~	~~inflateSetDictionary [1]~~

14.3 Data Definitions for libz

This section defines global identifiers and their values that are associated with interfaces contained in libz. These definitions are organized into groups that correspond to system headers. This convention is used as a convenience for the reader, and does not imply the existence of these headers, or their content.

~~These definitions are intended to supplement those provided in~~ Where an interface is defined as requiring a particular system header file all of the ~~referenced underlying~~data definitions for that system header file presented here shall be in effect.

This section gives data definitions to promote binary application portability, not to repeat source interface definitions available elsewhere. System providers and application developers should use this ABI to supplement - not to replace - source interface definition specifications.

This specification uses ~~ISO/IEC 9899~~the ISO C (1999) C Language as the reference programming language, and data definitions are specified in ISO C format. The C

language is used here as a convenient notation. Using a C language description of these data objects does not preclude their use by other programming languages.

14.3.1 zlib.h

In addition to the values below, the `zlib.h` header shall define the `ZLIB_VERSION` macro. This macro may be used to check that the version of the library at run time matches that at compile time.

See also the `zlibVersion()` function, which returns the library version at run time. The first character of the version at compile time should always match the first character at run time.

```
#define Z_NULL  0
#define MAX_WBITS       15
#define MAX_MEM_LEVEL   9
#define deflateInit2(strm,level,method,windowBits,memLevel,strategy)
\

extern uLong compressBound(uLong);
```

14.4 Interface Definitions for libz

The ~~following~~ interfaces defined on the following pages are included in libz and are defined by this specification. Unless otherwise noted, these interfaces shall be included in the source standard.

Other interfaces listed ~~above for libz~~in Section 14.2 shall behave as described in the referenced base document.

adler32

Name

adler32 — compute Adler 32 Checksum

Synopsis

```
#include <zlib.h>
uLong adler32(uLong adler, const Bytef * buf, uInt len);
```

Description

The adler32() function shall compute a running Adler-32 checksum (as described in RFC 1950: ZLIB Compressed Data Format Specication). On entry, *adler* is the previous value for the checksum, and *buf* shall point to an array of *len* bytes of data to be added to this checksum. The adler32() function shall return the new checksum.

If *buf* is NULL (or Z_NULL), adler32() shall return the initial checksum.

Return Value

The adler32() function shall return the new checksum value.

Errors

None defined.

Application Usage (informative)

The following code fragment demonstrates typical usage of the adler32() function:

```
uLong adler = adler32(0L, Z_NULL, 0);

while (read_buffer(buffer, length) != EOF) {
  adler = adler32(adler, buffer, length);
}
if (adler != original_adler) error();
```

compress

Name

`compress` — compress data

Synopsis

```
#include <zlib.h>
int compress(Bytef * dest, uLongf * destLen, const Bytef * source, uLong
sourceLen);
```

Description

The `compress()` function shall attempt to compress *`sourceLen`* bytes of data in the buffer *`source`*, placing the result in the buffer *`dest`*.

On entry, *`destLen`* should point to a value describing the size of the *`dest`* buffer. The application should ensure that this value be at least `(sourceLen × 1.001) + 12`. On successful exit, the variable referenced by *`destLen`* shall be updated to hold the length of compressed data in *`dest`*.

The `compress()` function is equivalent to `compress2()` with a *`level`* of `Z_DEFAULT_LEVEL`.

Return Value

On success, `compress()` shall return Z_OK. Otherwise, `compress()` shall return a value to indicate the error.

Errors

On error, `compress()` shall return a value as described below:

`Z_BUF_ERROR`

The buffer *`dest`* was not large enough to hold the compressed data.

`Z_MEM_ERROR`

Insufficient memory.

compress2

Name

`compress2` — compress data at a specified level

Synopsis

```
#include <zlib.h>
int compress2(Bytef * dest, uLongf * destLen, const Bytef * source, uLong
sourceLen, int level);
```

Description

The `compress2()` function shall attempt to compress *`sourceLen`* bytes of data in the buffer *`source`*, placing the result in the buffer *`dest`*, at the level described by *`level`*. The *`level`* supplied shall be a value between `0` and `9`, or the value `Z_DEFAULT_COMPRESSION`. A *`level`* of `1` requests the highest speed, while a *`level`* of `9` requests the highest compression. A *`level`* of `0` indicates that no compression should be used, and the output shall be the same as the input.

On entry, *`destLen`* should point to a value describing the size of the *`dest`* buffer. The application should ensure that this value be at least `(sourceLen × 1.001) + 12`. On successful exit, the variable referenced by *`destLen`* shall be updated to hold the length of compressed data in *`dest`*.

The `compress()` function is equivalent to `compress2()` with a *`level`* of `Z_DEFAULT_LEVEL`.

Return Value

On success, `compress2()` shall return Z_OK. Otherwise, `compress2()` shall return a value to indicate the error.

Errors

On error, `compress2()` shall return a value as described below:

`Z_BUF_ERROR`

: The buffer *`dest`* was not large enough to hold the compressed data.

`Z_MEM_ERROR`

: Insufficient memory.

`Z_STREAM_ERROR`

: The *`level`* was not `Z_DEFAULT_LEVEL`, or was not between 0 and 9.

compressBound

Name

`compressBound` — compute compressed data size

Synopsis

```
#include <zlib.h>
int compressBound(uLong sourceLen);
```

Description

The `compressBound()` function shall estimate the size of buffer required to compress *`sourceLen`* bytes of data using the `compress()` or `compress2()` functions. If successful, the value returned shall be an upper bound for the size of buffer required to compress *`sourceLen`* bytes of data, using the parameters stored in *`stream`*, in a single call to `compress()` or `compress2()`.

Return Value

The `compressBound()` shall return a value representing the upper bound of an array to allocate to hold the compressed data in a single call to `compress()` or `compress2()`. This function may return a conservative value that may be larger than *`sourceLen`*.

Errors

None defined.

crc32

Name

crc32 — compute CRC-32 Checksum

Synopsis

```
#include <zlib.h>
uLong crc32(uLong crc, const Bytef * buf, uInt len);
```

Description

The crc32() function shall compute a running Cyclic Redundancy Check checksum, as defined in ITU-T V.42. On entry, *crc* is the previous value for the checksum, and *buf* shall point to an array of *len* bytes of data to be added to this checksum. The crc32() function shall return the new checksum.

If *buf* is NULL (or Z_NULL), crc32() shall return the initial checksum.

Return Value

The crc32() function shall return the new checksum value.

Errors

None defined.

Application Usage (informative)

The following code fragment demonstrates typical usage of the crc32() function:

```
uLong crc = crc32(0L, Z_NULL, 0);

while (read_buffer(buffer, length) != EOF) {
  crc = crc32(crc, buffer, length);
}
if (crc != original_crc) error();
```

deflate

Name

`deflate` — compress data

Synopsis

```
#include <zlib.h>
int deflate(z_streamp stream, int flush);
```

Description

The `deflate()` function shall attempt to compress data until either the input buffer is empty or the output buffer is full. The *`stream`* references a `z_stream` structure. Before the first call to `deflate()`, this structure should have been initialized by a call to `deflateInit2_()`.

> **Note:** `deflateInit2_()` is only in the binary standard; source level applications should initialize *`stream`* via a call to `deflateInit()` or `deflateInit2()`.

In addition, the *`stream`* input and output buffers should have been initialized as follows:

`next_in`
: should point to the data to be compressed.

`avail_in`
: should contain the number of bytes of data in the buffer referenced by *`next_in`*.

`next_out`
: should point to a buffer where compressed data may be placed.

`avail_out`
: should contain the size in bytes of the buffer referenced by *`next_out`*

The `deflate()` function shall perform one or both of the following actions:

1. Compress input data from *`next_in`* and update *`next_in`*, *`avail_in`* and *`total_in`* to reflect the data that has been compressed.
2. Fill the output buffer referenced by *`next_out`*, and update *`next_out`*, *`avail_out`* and *`total_out`* to reflect the compressed data that has been placed there. If *`flush`* is not `Z_NO_FLUSH`, and *`avail_out`* indicates that there is still space in output buffer, this action shall always occur (see below for further details).

The `deflate()` function shall return when either *`avail_in`* reaches zero (indicating that all the input data has been compressed), or *`avail_out`* reaches zero (indicating that the output buffer is full).

On success, the `deflate()` function shall set the *`adler`* field of the *`stream`* to the `adler32()` checksum of all the input data compressed so far (represented by *`total_in`*).

If the deflate() function shall attempt to determine the type of input data, and set field *data_type* in *stream* to Z_ASCII if the majority of the data bytes fall within the ASCII (ISO 646) printable character range. Otherwise, it shall set *data_type* to Z_BINARY. This data type is informational only, and does not affect the compression algorithm.

> **Note:** Future versions of the LSB may remove this requirement, since it is based on an outdated character set that does not support Internationalization, and does not affect the algorithm. It is included for information only at this release. Applications should not depend on this field.

Flush Operation

The parameter *flush* determines when compressed bits are added to the output buffer in *next_out*. If *flush* is Z_NO_FLUSH, deflate() may return with some data pending output, and not yet added to the output buffer.

If *flush* is Z_SYNC_FLUSH, deflate() shall flush all pending output to *next_out* and align the output to a byte boundary. A synchronization point is generated in the output.

If *flush* is Z_FULL_FLUSH, all output shall be flushed, as for Z_SYNC_FLUSH, and the compression state shall be reset. A synchronization point is generated in the output.

> **Rationale:** Z_SYNC_FLUSH is intended to ensure that the compressed data contains all the data compressed so far, and allows a decompressor to reconstruct all of the input data. Z_FULL_FLUSH allows decompression to restart from this point if the previous compressed data has been lost or damaged. Flushing is likely to degrade the performance of the compression system, and should only be used where necessary.

If *flush* is set to Z_FINISH, all pending input shall be processed and deflate() shall return with Z_STREAM_END if there is sufficient space in the output buffer at *next_out*, as indicated by *avail_out*. If deflate() is called with *flush* set to Z_FINISH and there is insufficient space to store the compressed data, and no other error has occurred during compression, deflate() shall return Z_OK, and the application should call deflate() again with *flush* unchanged, and having updated *next_out* and *avail_out*.

If all the compression is to be done in a single step, deflate() may be called with *flush* set to Z_FINISH immediately after the stream has been initialized if *avail_out* is set to at least the value returned by deflateBound().

Return Value

On success, deflate() shall return Z_OK, unless *flush* was set to Z_FINISH and there was sufficient space in the output buffer to compress all of the input data. In this case, deflate() shall return Z_STREAM_END. On error, deflate() shall return a value to indicate the error.

> **Note:** If deflate() returns Z_OK and has set *avail_out* to zero, the function should be called again with the same value for *flush*, and with updated *next_out* and *avail_out* until deflate() returns with Z_OK (or Z_STREAM_END if *flush* is set to Z_FINISH) and a non-zero *avail_out*.

Errors

On error, deflate() shall return a value as described below, and set the *msg* field of *stream* to point to a string describing the error:

`Z_BUF_ERROR`

No progress is possible; either *`avail_in`* or *`avail_out`* was zero.

`Z_MEM_ERROR`

Insufficient memory.

`Z_STREAM_ERROR`

The state (as represented in *`stream`*) is inconsistent, or *`stream`* was `NULL`.

deflateBound

Name

`deflateBound` — compute compressed data size

Synopsis

```
#include <zlib.h>
int deflateBound(z_streamp stream, uLong sourceLen);
```

Description

The `deflateBound()` function shall estimate the size of buffer required to compress *`sourceLen`* bytes of data. If successful, the value returned shall be an upper bound for the size of buffer required to compress *`sourceLen`* bytes of data, using the parameters stored in *`stream`*, in a single call to `deflate()` with flush set to `Z_FINISH`.

On entry, *`stream`* should have been initialized via a call to `deflateInit_()` or `deflateInit2_()`.

Return Value

The `deflateBound()` shall return a value representing the upper bound of an array to allocate to hold the compressed data in a single call to `deflate()`. If the *`stream`* is not correctly initialized, or is `NULL`, then `deflateBound()` may return a conservative value that may be larger than *`sourceLen`*.

Errors

None defined.

deflateCopy

Name

`deflateCopy` — copy compression stream

Synopsis

```
#include <zlib.h>
int deflateCopy(z_streamp dest, z_streamp source);
```

Description

The `deflateCopy()` function shall copy the compression state information in *`source`* to the uninitialized `z_stream` structure referenced by *`dest`*.

On successful return, *`dest`* will be an exact copy of the stream referenced by *`source`*. The input and output buffer pointers in *`next_in`* and *`next_out`* will reference the same data.

Return Value

On success, `deflateCopy()` shall return Z_OK. Otherwise it shall return a value less than zero to indicate the error.

Errors

On error, `deflateCopy()` shall return a value as described below:

`Z_STREAM_ERROR`

The state in *`source`* is inconsistent, or either *`source`* or *`dest`* was `NULL`.

`Z_MEM_ERROR`

Insufficient memory available.

Application Usage (informative)

This function can be useful when several compression strategies will be tried, for example when there are several ways of pre-processing the input data with a filter. The streams that will be discarded should then be freed by calling `deflateEnd()`. Note that `deflateCopy()` duplicates the internal compression state which can be quite large, so this strategy may be slow and can consume lots of memory.

deflateEnd

Name

`deflateEnd` — free compression stream state

Synopsis

```
#include <zlib.h>
int deflateEnd(z_streamp stream);
```

Description

The `deflateEnd()` function shall free all allocated state information referenced by *`stream`*. All pending output is discarded, and unprocessed input is ignored.

Return Value

On success, `deflateEnd()` shall return Z_OK, or Z_DATA_ERROR if there was pending output discarded or input unprocessed. Otherwise it shall return Z_STREAM_ERROR to indicate the error.

Errors

On error, `deflateEnd()` shall return Z_STREAM_ERROR. The following conditions shall be treated as an error:

- The state in *`stream`* is inconsistent or inappropriate.
- *`stream`* is `NULL`.

deflateInit2_

Name

411 deflateInit2_ — initialize compression system

Synopsis

```
412 #include <zlib.h>
413  int deflateInit2_ (z_streamp strm, int level, int method, int windowBits,
414 int memLevel, int strategy, char * version, int stream_size);
```

Description

415 The deflateInit2_() function shall initialize the compression system. On entry,
416 *strm* shall refer to a user supplied z_stream object (a z_stream_s structure). The
417 following fields shall be set on entry:

418 *zalloc*

419 a pointer to an alloc_func function, used to allocate state information. If this is
420 NULL, a default allocation function will be used.

421 *zfree*

422 a pointer to a free_func function, used to free memory allocated by the *zalloc*
423 function. If this is NULL a default free function will be used.

424 *opaque*

425 If *alloc_func* is not NULL, *opaque* is a user supplied pointer to data that will be
426 passed to the *alloc_func* and *free_func* functions.

427 If the *version* requested is not compatible with the version implemented, or if the
428 size of the z_stream_s structure provided in *stream_size* does not match the size
429 in the library implementation, deflateInit2_() shall fail, and return
430 Z_VERSION_ERROR.

431 The *level* supplied shall be a value between 0 and 9, or the value
432 Z_DEFAULT_COMPRESSION. A *level* of 1 requests the highest speed, while a *level* of
433 9 requests the highest compression. A *level* of 0 indicates that no compression
434 should be used, and the output shall be the same as the input.

435 The *method* selects the compression algorithm to use. LSB conforming
436 implementation shall support the Z_DEFLATED method, and may support other
437 implementation defined methods.

438 The *windowBits* parameter shall be a base 2 logarithm of the window size to use,
439 and shall be a value between 8 and 15. A smaller value will use less memory, but
440 will result in a poorer compression ratio, while a higher value will give better
441 compression but utilize more memory.

442 The *memLevel* parameter specifies how much memory to use for the internal state.
443 The value of *memLevel* shall be between 1 and MAX_MEM_LEVEL. Smaller values use
444 less memory but are slower, while higher values use more memory to gain
445 compression speed.

446 The *strategy* parameter selects the compression strategy to use:

447 Z_DEFAULT_STRATEGY

448 use the system default compression strategy. `Z_DEFAULT_STRATEGY` is
449 particularly appropriate for text data.

450 `Z_FILTERED`

451 use a compression strategy tuned for data consisting largely of small values
452 with a fairly random distribution. `Z_FILTERED` uses more Huffman encoding
453 and less string matching than `Z_DEFAULT_STRATEGY`.

454 `Z_HUFFMAN_ONLY`

455 force Huffman encoding only, with no string match.

456 The `deflateInit2_()` function is not in the source standard; it is only in the binary
457 standard. Source applications should use the `deflateInit2()` macro.

Return Value

458 On success, the `deflateInit2_()` function shall return `Z_OK`. Otherwise,
459 `deflateInit2_()` shall return a value as described below to indicate the error.

Errors

460 On error, `deflateInit2_()` shall return one of the following error indicators:

461 `Z_STREAM_ERROR`

462 Invalid parameter.

463 `Z_MEM_ERROR`

464 Insufficient memory available.

465 `Z_VERSION_ERROR`

466 The version requested is not compatible with the library version, or the
467 z_stream size differs from that used by the library.

468 In addition, the *`msg`* field of the *`strm`* may be set to an error message.

deflateInit_

Name

`deflateInit_` — initialize compression system

Synopsis

```
#include <zlib.h>
int deflateInit_(z_streamp stream, int level, const char * version, int
stream_size);
```

Description

The `deflateInit_()` function shall initialize the compression system. On entry, *`stream`* shall refer to a user supplied z_stream object (a `z_stream_s` structure). The following fields shall be set on entry:

`zalloc`

a pointer to an alloc_func function, used to allocate state information. If this is `NULL`, a default allocation function will be used.

`zfree`

a pointer to a free_func function, used to free memory allocated by the *`zalloc`* function. If this is `NULL` a default free function will be used.

`opaque`

If *`alloc_func`* is not `NULL`, *`opaque`* is a user supplied pointer to data that will be passed to the *`alloc_func`* and *`free_func`* functions.

If the *`version`* requested is not compatible with the version implemented, or if the size of the `z_stream_s` structure provided in *`stream_size`* does not match the size in the library implementation, `deflateInit_()` shall fail, and return `Z_VERSION_ERROR`.

The *`level`* supplied shall be a value between `0` and `9`, or the value `Z_DEFAULT_COMPRESSION`. A *`level`* of `1` requests the highest speed, while a *`level`* of `9` requests the highest compression. A *`level`* of `0` indicates that no compression should be used, and the output shall be the same as the input.

The `deflateInit_()` function is not in the source standard; it is only in the binary standard. Source applications should use the `deflateInit()` macro.

The `deflateInit_()` function is equivalent to

```
 deflateInit2_(stream, level, Z_DEFLATED, MAX_WBITS, DEF_MEM_LEVEL,
```

```
                                    Z_DEFAULT_STRATEGY, version, stream_size);
```

Return Value

On success, the `deflateInit_()` function shall return `Z_OK`. Otherwise, `deflateInit_()` shall return a value as described below to indicate the error.

Errors

On error, `deflateInit_()` shall return one of the following error indicators:

`Z_STREAM_ERROR`

: Invalid parameter.

`Z_MEM_ERROR`

: Insufficient memory available.

`Z_VERSION_ERROR`

: The version requested is not compatible with the library version, or the z_stream size differs from that used by the library.

In addition, the *`msg`* field of the *`stream`* may be set to an error message.

deflateParams

Name

`deflateParams` — set compression parameters

Synopsis

```
#include <zlib.h>
int deflateParams(z_streamp stream, int level, int strategy);
```

Description

The `deflateParams()` function shall dynamically alter the compression parameters for the compression stream object *`stream`*. On entry, *`stream`* shall refer to a user supplied z_stream object (a `z_stream_s` structure), already initialized via a call to `deflateInit_()` or `deflateInit2_()`.

The *`level`* supplied shall be a value between `0` and `9`, or the value `Z_DEFAULT_COMPRESSION`. A *`level`* of `1` requests the highest speed, while a *`level`* of `9` requests the highest compression. A *`level`* of `0` indicates that no compression should be used, and the output shall be the same as the input. If the compression level is altered by `deflateParams()`, and some data has already been compressed with this *`stream`* (i.e. *`total_in`* is not zero), and the new *`level`* requires a different underlying compression method, then *`stream`* shall be flushed by a call to `deflate()`.

The *`strategy`* parameter selects the compression strategy to use:

`Z_DEFAULT_STRATEGY`

: use the system default compression strategy. `Z_DEFAULT_STRATEGY` is particularly appropriate for text data.

`Z_FILTERED`

: use a compression strategy tuned for data consisting largely of small values with a fairly random distribution. `Z_FILTERED` uses more Huffman encoding and less string matching than `Z_DEFAULT_STRATEGY`.

`Z_HUFFMAN_ONLY`

: force Huffman encoding only, with no string match.

Return Value

On success, the `deflateParams()` function shall return `Z_OK`. Otherwise, `deflateParams()` shall return a value as described below to indicate the error.

Errors

On error, `deflateParams()` shall return one of the following error indicators:

`Z_STREAM_ERROR`

: Invalid parameter.

`Z_MEM_ERROR`

: Insufficient memory available.

Z_BUF_ERROR

Insufficient space in *stream* to flush the current output.

In addition, the *msg* field of the *strm* may be set to an error message.

Application Usage (Informative)

Applications should ensure that the *stream* is flushed, e.g. by a call to **deflate(stream, Z_SYNC_FLUSH)** before calling deflateParams(), or ensure that there is sufficient space in *next_out* (as identified by *avail_out*) to ensure that all pending output and all uncompressed input can be flushed in a single call to deflate().

Rationale: Although the deflateParams() function should flush pending output and compress all pending input, the result is unspecified if there is insufficient space in the output buffer. Applications should only call deflateParams() when the *stream* is effectively empty (flushed).

The deflateParams() can be used to switch between compression and straight copy of the input data, or to switch to a different kind of input data requiring a different strategy.

deflateReset

Name

deflateReset — reset compression stream state

Synopsis

```
#include <zlib.h>
int deflateReset(z_streamp stream);
```

Description

The deflateReset() function shall reset all state associated with *stream*. All pending output shall be discarded, and the counts of processed bytes (*total_in* and *total_out*) shall be reset to zero.

Return Value

On success, deflateReset() shall return Z_OK. Otherwise it shall return Z_STREAM_ERROR to indicate the error.

Errors

On error, deflateReset() shall return Z_STREAM_ERROR. The following conditions shall be treated as an error:

- The state in *stream* is inconsistent or inappropriate.
- *stream* is NULL.

deflateSetDictionary

Name

`deflateSetDictionary` — initialize compression dictionary

Synopsis

```
#include <zlib.h>
int deflateSetDictionary(z_streamp stream, const Bytef * dictionary, uInt
dictlen);
```

Description

The `deflateSetDictionary()` function shall initialize the compression dictionary associated with *`stream`* using the *`dictlen`* bytes referenced by *`dictionary`*.

The implementation may silently use a subset of the provided dictionary if the dictionary cannot fit in the current window associated with *`stream`* (see `deflateInit2_()`). The application should ensure that the dictionary is sorted such that the most commonly used strings occur at the end of the dictionary.

If the dictionary is successfully set, the Adler32 checksum of the entire provided dictionary shall be stored in the *`adler`* member of *`stream`*. This value may be used by the decompression system to select the correct dictionary. The compression and decompression systems must use the same dictionary.

`stream` shall reference an initialized compression stream, with *`total_in`* zero (i.e. no data has been compressed since the stream was initialized).

Return Value

On success, `deflateSetDictionary()` shall return Z_OK. Otherwise it shall return Z_STREAM_ERROR to indicate an error.

Errors

On error, `deflateSetDictionary()` shall return a value as described below:

`Z_STREAM_ERROR`

: The state in *`stream`* is inconsistent, or *`stream`* was `NULL`.

Application Usage (informative)

The application should provide a dictionary consisting of strings {{{ed note: do we really mean "strings"? Null terminated?}}} that are likely to be encountered in the data to be compressed. The application should ensure that the dictionary is sorted such that the most commonly used strings occur at the end of the dictionary.

The use of a dictionary is optional; however if the data to be compressed is relatively short and has a predictable structure, the use of a dictionary can substantially improve the compression ratio.

get_crc_table

Name

`get_crc_table` — generate a table for crc calculations

Synopsis

```
#include <zlib.h>
const uLongf * get_crc_table(void);
```

Description

Generate tables for a byte-wise 32-bit CRC calculation based on the polynomial:
$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$

In a multi-threaded application, `get_crc_table()` should be called by one thread to initialize the tables before any other thread calls any `libz` function.

Return Value

The `get_crc_table()` function shall return a pointer to the first of a set of tables used internally to calculate CRC-32 values (see `crc32()`).

Errors

None defined.

gzclose

Name

`gzclose` — close a compressed file stream

Synopsis

```
#include <zlib.h>
 int gzclose (gzFile file );
```

Description

The `gzclose()` function shall close the compressed file stream *`file`*. If *`file`* was open for writing, `gzclose()` shall first flush any pending output. Any state information allocated shall be freed.

Return Value

On success, `gzclose()` shall return Z_OK. Otherwise, `gzclose()` shall return an error value as described below.

Errors

On error, `gzclose()` may set the global variable `errno` to indicate the error. The `gzclose()` shall return a value other than `Z_OK` on error.

`Z_STREAM_ERROR`

: *`file`* was `NULL` (or `Z_NULL`), or did not refer to an open compressed file stream.

`Z_ERRNO`

: An error occurred in the underlying base libraries, and the application should check `errno` for further information.

`Z_BUF_ERROR`

: no compression progress is possible during buffer flush (see `deflate()`).

gzdopen

Name

gzdopen — open a compressed file

Synopsis

```
#include <zlib.h>
 gzFile gzdopen ( int fd, const char *mode );
```

Description

The gzdopen() function shall attempt to associate the open file referenced by *fd* with a gzFile object. The *mode* argument is based on that of fopen(), but the *mode* parameter may also contain the following characters:

digit

set the compression level to *digit*. A low value (e.g. 1) means high speed, while a high value (e.g. 9) means high compression. A compression level of 0 (zero) means no compression. See defaultInit2_() for further details.

[fhR]

set the compression strategy to *[fhR]*. The letter f corresponds to filtered data, the letter h corresponds to Huffman only compression, and the letter R corresponds to Run Length Encoding. See defaultInit2_() for further details.

If *fd* refers to an uncompressed file, and *mode* refers to a read mode, gzdopen() shall attempt to open the file and return a gzFile object suitable for reading directly from the file without any decompression.

If *mode* is NULL, or if *mode* does not contain one of r, w, or a, gzdopen() shall return Z_NULL, and need not set any other error condition.

Example

```
gzdopen(fileno(stdin), "r");
```

Attempt to associate the standard input with a gzFile object.

Return Value

On success, gzdopen() shall return a gzFile object. On failure, gzdopen() shall return Z_NULL and may set errno accordingly.

Note: At version 1.2.2, zlib does not set errno for several error conditions. Applications may not be able to determine the cause of an error.

Errors

On error, gzdopen() may set the global variable errno to indicate the error.

gzeof

Name

`gzeof` — check for end-of-file on a compressed file stream

Synopsis

```
#include <zlib.h>
 int gzeof (gzFile file );
```

Description

The `gzeof()` function shall test the compressed file stream *`file`* for end of file.

Return Value

If *`file`* was open for reading and end of file has been reached, `gzeof()` shall return 1. Otherwise, `gzeof()` shall return 0.

Errors

None defined.

gzerror

Name

`gzerror` — decode an error on a compressed file stream

Synopsis

```
#include <zlib.h>
 const char * gzerror (gzFile file, int * errnum);
```

Description

The `gzerror()` function shall return a string describing the last error to have occurred associated with the open compressed file stream referred to by *`file`*. It shall also set the location referenced by *`errnum`* to an integer value that further identifies the error.

Return Value

The `gzerror()` function shall return a string that describes the last error associated with the given *`file`* compressed file stream. This string shall have the format `"%s: %s"`, with the name of the file, followed by a colon, a space, and the description of the error. If the compressed file stream was opened by a call to `gzdopen()`, the format of the filename is unspecified.

> **Rationale:** Although in all current implementations of libz file descriptors are named `"<fd:%d>"`, the code suggests that this is for debugging purposes only, and may change in a future release.

It is unspecified if the string returned is determined by the setting of the `LC_MESSAGES` category in the current locale.

Errors

None defined.

gzflush

Name

673 `gzflush` — flush a compressed file stream

Synopsis

```
674 #include <zlib.h>
675 int gzflush(gzFile file, int flush);
```

Description

676 The `gzflush()` function shall flush pending output to the compressed file stream
677 identified by *`file`*, which must be open for writing.

Flush Operation

678 The parameter *`flush`* determines which compressed bits are added to the output file.
679 If *`flush`* is `Z_NO_FLUSH`, `gzflush()` may return with some data pending output, and
680 not yet written to the file.

681 If *`flush`* is `Z_SYNC_FLUSH`, `gzflush()` shall flush all pending output to *`file`* and
682 align the output to a byte boundary. There may still be data pending compression
683 that is not flushed.

684 If *`flush`* is `Z_FULL_FLUSH`, all output shall be flushed, as for `Z_SYNC_FLUSH`, and the
685 compression state shall be reset. There may still be data pending compression that is
686 not flushed.

687 **Rationale:** `Z_SYNC_FLUSH` is intended to ensure that the compressed data contains all the
688 data compressed so far, and allows a decompressor to reconstruct all of the input data.
689 `Z_FULL_FLUSH` allows decompression to restart from this point if the previous
690 compressed data has been lost or damaged. Flushing is likely to degrade the
691 performance of the compression system, and should only be used where necessary.

692 If *`flush`* is set to `Z_FINISH`, all pending uncompressed data shall be compressed and
693 all output shall be flushed.

Return Value

694 On success, `gzflush()` shall return the value Z_OK. Otherwise `gzflush()` shall
695 return a value to indicate the error, and may set the error number associated with
696 the compressed file stream *`file`*.

697 **Note:** If *`flush`* is set to `Z_FINISH` and the flush operation is successful, `gzflush()` will
698 return Z_OK, but the compressed file stream error value may be set to `Z_STREAM_END`.

Errors

699 On error, `gzwrite()` shall return an error value, and may set the error number
700 associated with the stream identified by *`file`* to indicate the error. Applications may
701 use `gzerror()` to access this error value.

702 `Z_ERRNO`

703 An underlying base library function has indicated an error. The global variable
704 `errno` may be examined for further information.

705 `Z_STREAM_ERROR`

The stream is invalid, is not open for writing, or is in an invalid state.

`Z_BUF_ERROR`

no compression progress is possible (see `deflate()`).

`Z_MEM_ERROR`

Insufficient memory available to compress.

gzgetc

Name

`gzgetc` — read a character from a compressed file

Synopsis

```
#include <zlib.h>
 int gzgetc (gzFile file);
```

Description

The `gzgetc()` function shall read the next single character from the compressed file stream referenced by *`file`*, which shall have been opened in a read mode (see `gzopen()` and `gzdopen()`).

Return Value

On success, `gzgetc()` shall return the uncompressed character read, otherwise, on end of file or error, `gzgetc()` shall return -1.

Errors

On end of file or error, `gzgetc()` shall return -1. Further information can be found by calling `gzerror()` with a pointer to the compressed file stream.

gzgets

Name

`gzgets` — read a string from a compressed file

Synopsis

```
#include <zlib.h>
 char * gzgets (gzFile file, char * buf, int len);
```

Description

The `gzgets()` function shall attempt to read data from the compressed file stream *`file`*, uncompressing it into *`buf`* until either *`len`*`-1` bytes have been inserted into *`buf`*, or until a newline character has been uncompressed into *`buf`*. A null byte shall be appended to the uncompressed data. The *`file`* shall have been opened in for reading (see `gzopen()` and `gzdopen()`).

Return Value

On success, `gzgets()` shall return a pointer to *`buf`*. Otherwise, `gzgets()` shall return Z_NULL. Applications may examine the cause using `gzerror()`.

Errors

On error, `gzgets()` shall return Z_NULL. The following conditions shall always be treated as an error:

`file` is `NULL`, or does not refer to a file open for reading;
`buf` is `NULL`;
`len` is less than or equal to zero.

gzopen

Name

gzopen — open a compressed file

Synopsis

```
#include <zlib.h>
 gzFile gzopen (const char *path , const char *mode );
```

Description

The gzopen() function shall open the compressed file named by *path*. The *mode* argument is based on that of fopen(), but the *mode* parameter may also contain the following characters:

digit

set the compression level to *digit*. A low value (e.g. 1) means high speed, while a high value (e.g. 9) means high compression. A compression level of 0 (zero) means no compression. See defaultInit2_() for further details.

[fhR]

set the compression strategy to *[fhR]*. The letter f corresponds to filtered data, the letter h corresponds to Huffman only compression, and the letter R corresponds to Run Length Encoding. See defaultInit2_() for further details.

If *path* refers to an uncompressed file, and *mode* refers to a read mode, gzopen() shall attempt to open the file and return a gzFile object suitable for reading directly from the file without any decompression.

If *path* or *mode* is NULL, or if *mode* does not contain one of r, w, or a, gzopen() shall return Z_NULL, and need not set any other error condition.

The gzFile object is also referred to as a compressed file stream.

Example

```
gzopen("file.gz", "w6h");
```

Attempt to create a new compressed file, file.gz, at compression level 6 using Huffman only compression.

Return Value

On success, gzopen() shall return a gzFile object (also known as a *compressed file stream*). On failure, gzopen() shall return Z_NULL and may set errno accordingly.

Note: At version 1.2.2, zlib does not set errno for several error conditions. Applications may not be able to determine the cause of an error.

Errors

On error, gzopen() may set the global variable errno to indicate the error.

gzprintf

Name

`gzprintf` — format data and compress

Synopsis

```
#include <zlib.h>
 int gzprintf (gzFile file, const char * fmt, ...);
```

Description

The `gzprintf()` function shall format data as for `fprintf()`, and write the resulting string to the compressed file stream *`file`*.

Return Value

The `gzprintf()` function shall return the number of uncompressed bytes actually written, or a value less than or equal to `0` in the event of an error.

Errors

If *`file`* is `NULL`, or refers to a compressed file stream that has not been opened for writing, `gzprintf()` shall return `Z_STREAM_ERROR`. Otherwise, errors are as for `gzwrite()`.

gzputc

Name

`gzputc` — write character to a compressed file

Synopsis

```
#include <zlib.h>
 int gzputc (gzFile file, int c);
```

Description

The `gzputc()` function shall write the single character *`c`*, converted from integer to unsigned character, to the compressed file referenced by *`file`*, which shall have been opened in a write mode (see `gzopen()` and `gzdopen()`).

Return Value

On success, `gzputc()` shall return the value written, otherwise `gzputc()` shall return -1.

Errors

On error, `gzputc()` shall return -1.

gzputs

Name

`gzputs` — string write to a compressed file

Synopsis

```
#include <zlib.h>
 int gzputs (gzFile file, const char * s);
```

Description

The `gzputs()` function shall write the null terminated string `s` to the compressed file referenced by *`file`*, which shall have been opened in a write mode (see `gzopen()` and `gzdopen()`). The terminating null character shall not be written. The `gzputs()` function shall return the number of uncompressed bytes actually written.

Return Value

On success, `gzputs()` shall return the number of uncompressed bytes actually written to *`file`*. On error `gzputs()` shall return a value less than or equal to `0`. Applications may examine the cause using `gzerror()`.

Errors

On error, `gzputs()` shall set the error number associated with the stream identified by *`file`* to indicate the error. Applications should use `gzerror()` to access this error value. If *`file`* is `NULL`, `gzputs()` shall return `Z_STREAM_ERR`.

`Z_ERRNO`

An underlying base library function has indicated an error. The global variable `errno` may be examined for further information.

`Z_STREAM_ERROR`

The stream is invalid, is not open for writing, or is in an invalid state.

`Z_BUF_ERROR`

no compression progress is possible (see `deflate()`).

`Z_MEM_ERROR`

Insufficient memory available to compress.

gzread

Name

`gzread` — read from a compressed file

Synopsis

```
#include <zlib.h>
 int gzread (gzFile file, voidp buf, unsigned int len);
```

Description

The `gzread()` function shall read data from the compressed file referenced by *`file`*, which shall have been opened in a read mode (see `gzopen()` and `gzdopen()`). The `gzread()` function shall read data from *`file`*, and uncompress it into *`buf`*. At most, *`len`* bytes of uncompressed data shall be copied to *`buf`*. If the file is not compressed, `gzread()` shall simply copy data from *`file`* to *`buf`* without alteration.

Return Value

On success, `gzread()` shall return the number of bytes decompressed into *`buf`*. If `gzread()` returns `0`, either the end-of-file has been reached or an underlying read error has occurred. Applications should use `gzerror()` or `gzeof()` to determine which occurred. On other errors, `gzread()` shall return a value less than `0` and and applications may examine the cause using `gzerror()`.

Errors

On error, `gzread()` shall set the error number associated with the stream identified by *`file`* to indicate the error. Applications should use `gzerror()` to access this error value.

`Z_ERRNO`

: An underlying base library function has indicated an error. The global variable `errno` may be examined for further information.

`Z_STREAM_END`

: End of file has been reached on input.

`Z_DATA_ERROR`

: A CRC error occurred when reading data; the file is corrupt.

`Z_STREAM_ERROR`

: The stream is invalid, or is in an invalid state.

`Z_NEED_DICT`

: A dictionary is needed (see `inflateSetDictionary()`).

`Z_MEM_ERROR`

: Insufficient memory available to decompress.

gzrewind

Name

gzrewind — reset the file-position indicator on a compressed file stream

Synopsis

```
#include <zlib.h>
int gzrewind(gzFile file);
```

Description

The gzrewind() function shall set the starting position for the next read on compressed file stream *file* to the beginning of file. *file* must be open for reading.

gzrewind() is equivalent to

```
(int)gzseek(file, 0L, SEEK_SET)
```

.

Return Value

On success, gzrewind() shall return 0. On error, gzrewind() shall return -1, and may set the error value for *file* accordingly.

Errors

On error, gzrewind() shall return -1, indicating that *file* is NULL, or does not represent an open compressed file stream, or represents a compressed file stream that is open for writing and is not currently at the beginning of file.

gzseek

Name

gzseek — reposition a file-position indicator in a compressed file stream

Synopsis

```
#include <zlib.h>
z_off_t gzseek(gzFile file, z_off_t offset, int whence);
```

Description

The gzseek() function shall set the file-position indicator for the compressed file stream *file*. The file-position indicator controls where the next read or write operation on the compressed file stream shall take place. The *offset* indicates a byte offset in the uncompressed data. The *whence* parameter may be one of:

SEEK_SET

: the offset is relative to the start of the uncompressed data.

SEEK_CUR

: the offset is relative to the current positition in the uncompressed data.

: **Note:** The value SEEK_END need not be supported.

If the *file* is open for writing, the new offset must be greater than or equal to the current offset. In this case, gzseek() shall compress a sequence of null bytes to fill the gap from the previous offset to the new offset.

Return Value

On success, gzseek() shall return the resulting offset in the file expressed as a byte position in the *uncompressed* data stream. On error, gzseek() shall return -1, and may set the error value for *file* accordingly.

Errors

On error, gzseek() shall return -1. The following conditions shall always result in an error:

- *file* is NULL
- *file* does not represent an open compressed file stream.
- *file* refers to a compressed file stream that is open for writing, and the newly computed offset is less than the current offset.
- The newly computed offset is less than zero.
- *whence* is not one of the supported values.

Application Usage (informative)

If *file* is open for reading, the implementation may still need to uncompress all of the data up to the new offset. As a result, gzseek() may be extremely slow in some circumstances.

gzsetparams

Name

`gzsetparams` — dynamically set compression parameters

Synopsis

```
#include <zlib.h>
 int gzsetparams (gzFile file, int level, int strategy);
```

Description

The `gzsetparams()` function shall set the compression level and compression strategy on the compressed file stream referenced by *`file`*. The compressed file stream shall have been opened in a write mode. The *`level`* and *`strategy`* are as defined in deflateInit2_. If there is any data pending writing, it shall be flushed before the parameters are updated.

Return Value

On success, the `gzsetparams()` function shall return `Z_OK`.

Errors

On error, `gzsetparams()` shall return one of the following error indications:

`Z_STREAM_ERROR`

: Invalid parameter, or *`file`* not open for writing.

`Z_BUF_ERROR`

: An internal inconsistency was detected while flushing the previous buffer.

gztell

Name

gztell — find position on a compressed file stream

Synopsis

```
#include <zlib.h>
 z_off_t gztell (gzFile file );
```

Description

The gztell() function shall return the starting position for the next read or write operation on compressed file stream *file*. This position represents the number of bytes from the beginning of file in the uncompressed data.

gztell() is equivalent to

```
gzseek(file, 0L, SEEK_SET)
```

.

Return Value

gztell() shall return the current offset in the file expressed as a byte position in the *uncompressed* data stream. On error, gztell() shall return -1, and may set the error value for *file* accordingly.

Errors

On error, gztell() shall return -1, indicating that *file* is NULL, or does not represent an open compressed file stream.

gzwrite

Name

`gzwrite` — write to a compressed file

Synopsis

```
#include <zlib.h>
 int gzwrite (gzFile file, voidpc buf, unsigned int len);
```

Description

The `gzwrite()` function shall write data to the compressed file referenced by *`file`*, which shall have been opened in a write mode (see `gzopen()` and `gzdopen()`). On entry, *`buf`* shall point to a buffer containing *`len`*bytes of uncompressed data. The `gzwrite()` function shall compress this data and write it to *`file`*. The `gzwrite()` function shall return the number of uncompressed bytes actually written.

Return Value

On success, `gzwrite()` shall return the number of uncompressed bytes actually written to *`file`*. On error `gzwrite()` shall return a value less than or equal to `0`. Applications may examine the cause using `gzerror()`.

Errors

On error, `gzwrite()` shall set the error number associated with the stream identified by *`file`* to indicate the error. Applications should use `gzerror()` to access this error value.

`Z_ERRNO`

: An underlying base library function has indicated an error. The global variable `errno` may be examined for further information.

`Z_STREAM_ERROR`

: The stream is invalid, is not open for writing, or is in an invalid state.

`Z_BUF_ERROR`

: no compression progress is possible (see `deflate()`).

`Z_MEM_ERROR`

: Insufficient memory available to compress.

inflate

Name

`inflate` — decompress data

Synopsis

```
#include <zlib.h>
int inflate(z_streamp stream, int flush);
```

Description

The `inflate()` function shall attempt to decompress data until either the input buffer is empty or the output buffer is full. The *`stream`* references a `z_stream` structure. Before the first call to `inflate()`, this structure should have been initialized by a call to `inflateInit2_()`.

> **Note:** `inflateInit2_()` is only in the binary standard; source level applications should initialize *`stream`* via a call to `inflateInit()` or `inflateInit2()`.

In addition, the *`stream`* input and output buffers should have been initialized as follows:

`next_in`
: should point to the data to be decompressed.

`avail_in`
: should contain the number of bytes of data in the buffer referenced by *`next_in`*.

`next_out`
: should point to a buffer where decompressed data may be placed.

`avail_out`
: should contain the size in bytes of the buffer referenced by *`next_out`*

The `inflate()` function shall perform one or both of the following actions:

1. Decompress input data from *`next_in`* and update *`next_in`*, *`avail_in`* and *`total_in`* to reflect the data that has been decompressed.
2. Fill the output buffer referenced by *`next_out`*, and update *`next_out`*, *`avail_out`*, and *`total_out`* to reflect the decompressed data that has been placed there. If *`flush`* is not `Z_NO_FLUSH`, and *`avail_out`* indicates that there is still space in output buffer, this action shall always occur (see below for further details).

The `inflate()` function shall return when either *`avail_in`* reaches zero (indicating that all the input data has been compressed), or *`avail_out`* reaches zero (indicating that the output buffer is full).

On success, the `inflate()` function shall set the *`adler`* field of the *`stream`* to the Adler-32 checksum of all the input data compressed so far (represented by *`total_in`*).

Flush Operation

The parameter *flush* determines when uncompressed bytes are added to the output buffer in *next_out*. If *flush* is Z_NO_FLUSH, inflate() may return with some data pending output, and not yet added to the output buffer.

If *flush* is Z_SYNC_FLUSH, inflate() shall flush all pending output to *next_out*, and update *next_out* and *avail_out* accordingly.

If *flush* is set to Z_BLOCK, inflate() shall stop adding data to the output buffer if and when the next compressed block boundary is reached (see RFC 1951: DEFLATE Compressed Data Format Specification).

If *flush* is set to Z_FINISH, all of the compressed input shall be decompressed and added to the output. If there is insufficient output space (i.e. the compressed input data uncompresses to more than *avail_out* bytes), then inflate() shall fail and return Z_BUF_ERROR.

Return Value

On success, inflate() shall return Z_OK if decompression progress has been made, or Z_STREAM_END if all of the input data has been decompressed and there was sufficient space in the output buffer to store the uncompressed result. On error, inflate() shall return a value to indicate the error.

> **Note:** If inflate() returns Z_OK and has set *avail_out* to zero, the function should be called again with the same value for *flush*, and with updated *next_out* and *avail_out* until inflate() returns with either Z_OK or Z_STREAM_END and a non-zero *avail_out*.

On success, inflate() shall set the *adler* to the Adler-32 checksum of the output produced so far (i.e. *total_out* bytes).

Errors

On error, inflate() shall return a value as described below, and may set the *msg* field of *stream* to point to a string describing the error:

Z_BUF_ERROR

: No progress is possible; either *avail_in* or *avail_out* was zero.

Z_MEM_ERROR

: Insufficient memory.

Z_STREAM_ERROR

: The state (as represented in *stream*) is inconsistent, or *stream* was NULL.

Z_NEED_DICT

: A preset dictionary is required. The *adler* field shall be set to the Adler-32 checksum of the dictionary chosen by the compressor.

inflateEnd

Name

`inflateEnd` — free decompression stream state

Synopsis

```
#include <zlib.h>
int inflateEnd(z_streamp stream);
```

Description

The `inflateEnd()` function shall free all allocated state information referenced by *`stream`*. All pending output is discarded, and unprocessed input is ignored.

Return Value

On success, `inflateEnd()` shall return Z_OK. Otherwise it shall return Z_STREAM_ERROR to indicate the error.

Errors

On error, `inflateEnd()` shall return Z_STREAM_ERROR. The following conditions shall be treated as an error:

- The state in *`stream`* is inconsistent.
- *`stream`* is `NULL`.
- The *`zfree`* function pointer is `NULL`.

inflateInit2_

Name

inflateInit2_ — initialize decompression system

Synopsis

```
#include <zlib.h>
 int inflateInit2_ (z_streamp strm, int windowBits, char * version, int
stream_size);
```

Description

The inflateInit2_() function shall initialize the decompression system. On entry, *strm* shall refer to a user supplied z_stream object (a z_stream_s structure). The following fields shall be set on entry:

zalloc

: a pointer to an alloc_func function, used to allocate state information. If this is NULL, a default allocation function will be used.

zfree

: a pointer to a free_func function, used to free memory allocated by the *zalloc* function. If this is NULL a default free function will be used.

opaque

: If *alloc_func* is not NULL, *opaque* is a user supplied pointer to data that will be passed to the *alloc_func* and *free_func* functions.

If the *version* requested is not compatible with the version implemented, or if the size of the z_stream_s structure provided in *stream_size* does not match the size in the library implementation, inflateInit2_() shall fail, and return Z_VERSION_ERROR.

The *windowBits* parameter shall be a base 2 logarithm of the maximum window size to use, and shall be a value between 8 and 15. If the input data was compressed with a larger window size, subsequent attempts to decompress this data will fail with Z_DATA_ERROR, rather than try to allocate a larger window.

The inflateInit2_() function is not in the source standard; it is only in the binary standard. Source applications should use the inflateInit2() macro.

Return Value

On success, the inflateInit2_() function shall return Z_OK. Otherwise, inflateInit2_() shall return a value as described below to indicate the error.

Errors

On error, inflateInit2_() shall return one of the following error indicators:

Z_STREAM_ERROR

: Invalid parameter.

Z_MEM_ERROR

: Insufficient memory available.

`Z_VERSION_ERROR`

The version requested is not compatible with the library version, or the z_stream size differs from that used by the library.

In addition, the *`msg`* field of the *`strm`* may be set to an error message.

inflateInit_

Name

inflateInit_ — initialize decompression system

Synopsis

```
#include <zlib.h>
int inflateInit_(z_streamp stream, const char * version, int stream_size);
```

Description

The inflateInit_() function shall initialize the decompression system. On entry, *stream* shall refer to a user supplied z_stream object (a z_stream_s structure). The following fields shall be set on entry:

zalloc

a pointer to an alloc_func function, used to allocate state information. If this is NULL, a default allocation function will be used.

zfree

a pointer to a free_func function, used to free memory allocated by the *zalloc* function. If this is NULL a default free function will be used.

opaque

If *alloc_func* is not NULL, *opaque* is a user supplied pointer to data that will be passed to the *alloc_func* and *free_func* functions.

If the *version* requested is not compatible with the version implemented, or if the size of the z_stream_s structure provided in *stream_size* does not match the size in the library implementation, inflateInit_() shall fail, and return Z_VERSION_ERROR.

The inflateInit_() function is not in the source standard; it is only in the binary standard. Source applications should use the inflateInit() macro.

The inflateInit_() shall be equivalent to

```
inflateInit2_(strm, DEF_WBITS, version, stream_size);
```

Return Value

On success, the inflateInit_() function shall return Z_OK. Otherwise, inflateInit_() shall return a value as described below to indicate the error.

Errors

On error, inflateInit_() shall return one of the following error indicators:

Z_STREAM_ERROR

Invalid parameter.

Z_MEM_ERROR

Insufficient memory available.

Z_VERSION_ERROR

The version requested is not compatible with the library version, or the z_stream size differs from that used by the library.

In addition, the *msg* field of the *strm* may be set to an error message.

inflateReset

Name

`inflateReset` — reset decompression stream state

Synopsis

```
#include <zlib.h>
int inflateReset(z_streamp stream);
```

Description

The `inflateReset()` function shall reset all state associated with *stream*. All pending output shall be discarded, and the counts of processed bytes (*total_in* and *total_out*) shall be reset to zero.

Return Value

On success, `inflateReset()` shall return Z_OK. Otherwise it shall return Z_STREAM_ERROR to indicate the error.

Errors

On error, `inflateReset()` shall return Z_STREAM_ERROR. The following conditions shall be treated as an error:

- The state in *stream* is inconsistent or inappropriate.
- *stream* is `NULL`.

inflateSetDictionary

Name

`inflateSetDictionary` — initialize decompression dictionary

Synopsis

```
#include <zlib.h>
int inflateSetDictionary(z_streamp stream, const Bytef * dictionary, uInt
dictlen);
```

Description

The `inflateSetDictionary()` function shall initialize the decompression dictionary associated with *`stream`* using the *`dictlen`* bytes referenced by *`dictionary`*.

The `inflateSetDictionary()` function should be called immediately after a call to `inflate()` has failed with return value Z_NEED_DICT. The *`dictionary`* must have the same Adler-32 checksum as the dictionary used for the compression (see `deflateSetDictionary()`).

`stream` shall reference an initialized decompression stream, with *`total_in`* zero (i.e. no data has been decompressed since the stream was initialized).

Return Value

On success, `inflateSetDictionary()` shall return Z_OK. Otherwise it shall return a value as indicated below.

Errors

On error, `inflateSetDictionary()` shall return a value as described below:

`Z_STREAM_ERROR`

The state in *`stream`* is inconsistent, or *`stream`* was `NULL`.

`Z_DATA_ERROR`

The Adler-32 checksum of the supplied dictionary does not match that used for the compression.

Application Usage (informative)

The application should provide a dictionary consisting of strings {{{ed note: do we really mean "strings"? Null terminated?}}} that are likely to be encountered in the data to be compressed. The application should ensure that the dictionary is sorted such that the most commonly used strings occur at the end of the dictionary.

The use of a dictionary is optional; however if the data to be compressed is relatively short and has a predictable structure, the use of a dictionary can substantially improve the compression ratio.

inflateSync

Name

`inflateSync` — advance compression stream to next sync point

Synopsis

```
#include <zlib.h>
int inflateSync(z_streamp stream);
```

Description

The `inflateSync()` function shall advance through the compressed data in *`stream`*, skipping any invalid compressed data, until the next full flush point is reached, or all input is exhausted. See the description for `deflate()` with flush level `Z_FULL_FLUSH`. No output is placed in *`next_out`*.

Return Value

On success, `inflateSync()` shall return Z_OK, and update the *`next_in`*,, *`avail_in`*, and, *`total_in`* fields of *`stream`* to reflect the number of bytes of compressed data that have been skipped. Otherwise, `inflateSync()` shall return a value as described below to indicate the error.

Errors

On error, `inflateSync()` shall return a value as described below:

`Z_STREAM_ERROR`

: The state (as represented in *`stream`*) is inconsistent, or *`stream`* was `NULL`.

`Z_BUF_ERROR`

: There is no data available to skip over.

`Z_DATA_ERROR`

: No sync point was found.

inflateSyncPoint

Name

`inflateSyncPoint` — test for synchronization point

Synopsis

```
#include <zlib.h>
int inflateSyncPoint(z_streamp stream);
```

Description

The `inflateSyncPoint()` function shall return a non-zero calue if the compressed data stream referenced by *`stream`* is at a synchronization point.

Return Value

If the compressed data in *`stream`* is at a synchronization point (see `deflate()` with a flush level of `Z_SYNC_FLUSH` or `Z_FULL_FLUSH`), `inflateSyncPoint()` shall return a non-zero value, other than `Z_STREAM_ERROR`. Otherwise, if the *`stream`* is valid, `inflateSyncPoint()` shall return 0. If *`stream`* is invalid, or in an invalid state, `inflateSyncPoint()` shall return Z_STREAM_ERROR to indicate the error.

Errors

On error, `inflateSyncPoint()` shall return a value as described below:

`Z_STREAM_ERROR`

: The state (as represented in *`stream`*) is inconsistent, or *`stream`* was `NULL`.

uncompress

Name

uncompress — uncompress data

Synopsis

```
#include <zlib.h>
int uncompress(Bytef * dest, uLongf * destLen, const Bytef * source, uLong
sourceLen);
```

Description

The uncompress() function shall attempt to uncompress *sourceLen* bytes of data in the buffer *source*, placing the result in the buffer *dest*.

On entry, *destLen* should point to a value describing the size of the *dest* buffer. The application should ensure that this value is large enough to hold the entire uncompressed data.

> **Note:** The LSB does not describe any mechanism by which a compressor can communicate the size required to the uncompressor.

On successful exit, the variable referenced by *destLen* shall be updated to hold the length of uncompressed data in *dest*.

Return Value

On success, uncompress() shall return Z_OK. Otherwise, uncompress() shall return a value to indicate the error.

Errors

On error, uncompress() shall return a value as described below:

Z_BUF_ERROR

The buffer *dest* was not large enough to hold the uncompressed data.

Z_MEM_ERROR

Insufficient memory.

Z_DATA_ERROR

The compressed data (referenced by *source*) was corrupted.

zError

Name

zError — translate error number to string

Synopsis

```
#include <zlib.h>
const char * zError(int err);
```

Description

The zError() function shall return the string identifying the error associated with *err*. This allows for conversion from error code to string for functions such as compress() and uncompress(), that do not always set the string version of an error.

Return Value

The zError() function shall return a the string identifying the error associated with *err*, or NULL if *err* is not a valid error code.

It is unspecified if the string returned is determined by the setting of the LC_MESSAGES category in the current locale.

Errors

None defined.

zlibVersion

Name

zlibVersion — discover library version at run time

Synopsis

```
#include <zlib.h>
 const char * zlibVersion (void);
```

Description

The zlibVersion() function shall return the string identifying the interface version at the time the library was built.

Applications should compare the value returned from zlibVersion() with the macro constant ZLIB_VERSION for compatibility.

Return Value

The zlibVersion() function shall return a the string identifying the version of the library currently implemented.

Errors

None defined.

14.5 Interfaces for libncurses

Table 14-3 defines the library name and shared object name for the libncurses library

Table 14-3 libncurses Definition

Library:	libncurses
SONAME:	libncurses.so.5

The Parameters or return value of the following interface have had the const qualifier added as shown here.

```
extern const char *keyname (int);
extern int mvscanw (int, int, const char *, ...);
extern int mvwscanw (WINDOW *, int, int, const char *, ...);
extern SCREEN *newterm (const char *, FILE *, FILE *);
extern int scanw (const char *, ...);
extern int vwscanw (WINDOW *, const char *, va_list);
extern int vw_scanw (WINDOW *, const char *, va_list);
extern int wscanw (WINDOW *, const char *, ...);
```

The behavior of the interfaces in this library is specified by the following specifications:

[SUS-CURSES] X/Open Curses

14.5.1 Curses

14.5.1.1 Interfaces for Curses

An LSB conforming implementation shall provide the generic functions for Curses specified in Table 14-4, with the full mandatory functionality as described in the referenced underlying specification.

Table 14-4 libncurses - Curses Function Interfaces

14.6 Data Definitions for libncurses

This section defines global identifiers and their values that are associated with interfaces contained in libncurses. These definitions are organized into groups that correspond to system headers. This convention is used as a convenience for the reader, and does not imply the existence of these headers, or their content.

~~These definitions are intended to supplement those provided in~~ Where an interface is defined as requiring a particular system header file all of the ~~referenced underlying~~data definitions for that system header file presented here shall be in effect.

This section gives data definitions to promote binary application portability, not to repeat source interface definitions available elsewhere. System providers and application developers should use this ABI to supplement - not to replace - source interface definition specifications.

This specification uses ~~ISO/IEC 9899~~the ISO C (1999) C Language as the reference programming language, and data definitions are specified in ISO C format. The C language is used here as a convenient notation. Using a C language description of these data objects does not preclude their use by other programming languages.

14.7 Interfaces for libutil

Table 14-6 defines the library name and shared object name for the libutil library

Table 14-6 libutil Definition

Library:	libutil
SONAME:	libutil.so.1

The behavior of the interfaces in this library is specified by the following specifications:

[LSB] ~~this specification~~This Specification

14.7.1 Utility Functions

14.7.1.1 Interfaces for Utility Functions

An LSB conforming implementation shall provide the generic functions for Utility Functions specified in Table 14-7, with the full mandatory functionality as described in the referenced underlying specification.

1800 **Table 14-7 libutil - Utility Functions Function Interfaces**

~~forkpty [1]~~	~~login_tty [1]~~	~~logwtmp [1]~~		
~~login [1]~~	~~logout [1]~~	~~openpty [1]~~		

1801

1802 ~~*Referenced Specification(s)*~~

1803 ~~**[1].** this specification~~

forkpty [LSB]	login [LSB]	login_tty [LSB]	logout [LSB]
logwtmp [LSB]	openpty [LSB]		

1804

14.8 Interface Definitions for libutil

1805 The ~~following~~ interfaces defined on the following pages are included in libutil and
1806 are defined by this specification. Unless otherwise noted, these interfaces shall be
1807 included in the source standard.

1808 Other interfaces listed ~~above for libutil~~in Section 14.7 shall behave as described in
1809 the referenced base document.

forkpty

Name

`forkpty` — Create a new process attached to an available pseudo-terminal

Synopsis

```
#include <pty.h>
int forkpty(int * amaster, char * name, struct termios * termp, struct winsize
* winp);
```

Description

The `forkpty()` function shall find and open a pseudo-terminal device pair in the same manner as the `openpty()` function. If a pseudo-terminal is available, `forkpty()` shall create a new process in the same manner as the `fork()` function, and prepares the new process for login in the same manner as `login_tty()`.

If *`termp`* is not null, it shall refer to a `termios` structure that shall be used to initialize the characteristics of the slave device. If *`winp`* is not null, it shall refer to a `winsize` structure used to initialize the window size of the slave device.

Return Value

On success, the parent process shall return the process id of the child, and the child shall return 0. On error, no new process shall be created, -1 shall be returned, and `errno` shall be set appropriately. On success, the parent process shall receive the file descriptor of the master side of the pseudo-terminal in the location referenced by *`amaster`*, and, if *`name`* is not NULL, the filename of the slave device in *`name`*.

Errors

EAGAIN

: Unable to create a new process.

ENOENT

: There are no available pseudo-terminals.

ENOMEM

: Insufficient memory was available.

login

Name

`login` — login utility function

Synopsis

```
#include <utmp.h>
void login (struct utmp * ut );
```

Description

The `login()` function shall update the user accounting databases. The *`ut`* parameter shall reference a `utmp` structure for all fields except the following:

1. The *`ut_type`* field shall be set to `USER_PROCESS`.
2. The *`ut_pid`* field shall be set to the process identifier for the current process.
3. The *`ut_line`* field shall be set to the name of the controlling terminal device. The name shall be found by examining the device associated with the standard input, output and error streams in sequence, until one associated with a terminal device is found. If none of these streams refers to a terminal device, the *`ut_line`* field shall be set to `"???"`. If the terminal device is in the `/dev` directory hierarchy, the *`ut_line`* field shall not contain the leading `"/dev/"`, otherwise it shall be set to the final component of the pathname of the device. If the user accounting database imposes a limit on the size of the *`ut_line`* field, it shall truncate the name, but any such limit shall not be smaller than `UT_LINESIZE` (including a terminating null character).

Return Value

None

Errors

None

login_tty

Name

`login_tty` — Prepare a terminal for login

Synopsis

```
#include <utmp.h>
int login_tty (int fdr);
```

Description

The `login_tty()` function shall prepare the terminal device referenced by the file descriptor *`fdr`*. This function shall create a new session, make the terminal the controlling terminal for the current process, and set the standard input, output, and error streams of the current process to the terminal. If *`fdr`* is not the standard input, output or error stream, then `login_tty()` shall close *`fdr`*.

Return Value

On success, `login_tty()` shall return zero; otherwise -1 is returned, and errno shall be set appropriately.

Errors

ENOTTY

`fdr` does not refer to a terminal device.

logout

Name

`logout` — logout utility function

Synopsis

```
#include <utmp.h>
int logout (const char * line );
```

Description

Given the device *`line`*, the `logout()` function shall search the user accounting database which is read by `getutent()` for an entry with the corresponding line, and with the type of `USER_PROCESS`. If a corresponding entry is located, it shall be updated as follows:

1. The `ut_name` field shall be set to zeroes (`UT_NAMESIZE` NUL bytes).
2. The `ut_host` field shall be set to zeroes (`UT_HOSTSIZE` NUL bytes).
3. The `ut_tv` shall be set to the current time of day.
4. The `ut_type` field shall be set to `DEAD_PROCESS`.

Return Value

On success, the `logout()` function shall return non-zero. Zero is returned if there was no entry to remove, or if the utmp file could not be opened or updated.

logwtmp

Name

logwtmp — append an entry to the wtmp file

Synopsis

```
#include <utmp.h>
void logwtmp (const char * line , const char * name , const char * host );
```

Description

If the process has permission to update the user accounting databases, the `logwtmp()` function shall append a record to the user accounting database that records all logins and logouts. The record to be appended shall be constructed as follows:

1. The `ut_line` field shall be initialized from *`line`*. If the user accounting database imposes a limit on the size of the *`ut_line`* field, it shall truncate the value, but any such limit shall not be smaller than `UT_LINESIZE` (including a terminating null character).
2. The `ut_name` field shall be initialized from *`name`*. If the user accounting database imposes a limit on the size of the *`ut_name`* field, it shall truncate the value, but any such limit shall not be smaller than `UT_NAMESIZE` (including a terminating null character).
3. The `ut_host` field shall be initialized from *`host`*. If the user accounting database imposes a limit on the size of the *`ut_host`* field, it shall truncate the value, but any such limit shall not be smaller than `UT_HOSTSIZE` (including a terminating null character).
4. If the *`name`* parameter does not refer to an empty string (i.e. `""`), the `ut_type` field shall be set to `USER_PROCESS`; otherwise the `ut_type` field shall be set to `DEAD_PROCESS`.
5. The `ut_id` field shall be set to the process identifier for the current process.
6. The `ut_tv` field shall be set to the current time of day.

Note: If a process does not have write access to the the user accounting database, the `logwtmp()` function will not update it. Since the function does not return any value, an application has no way of knowing whether it succeeded or failed.

Return Value

None.

openpty

Name

`openpty` — find and open an available pseudo-terminal

Synopsis

```
#include <pty.h>
int openpty(int *amaster, int *aslave, char *name, struct termios *termp,
struct winsize *winp);
```

Description

The `openpty()` function shall find an available pseudo-terminal and return file descriptors for the master and slave devices in the locations referenced by *`amaster`* and *`aslave`* respectively. If *`name`* is not NULL, the filename of the slave shall be placed in the user supplied buffer referenced by *`name`*. If *`termp`* is not NULL, it shall point to a `termios` structure used to initialize the terminal parameters of the slave pseudo-terminal device. If *`winp`* is not NULL, it shall point to a `winsize` structure used to initialize the window size parameters of the slave pseudo-terminal device.

Return Value

On success, zero is returned. On error, -1 is returned, and errno is set appropriately.

Errors

ENOENT

There are no available pseudo-terminals.

V Commands and Utilities

15 Commands and Utilities

15.1 Commands and Utilities

An LSB conforming implementation shall provide the commands and utilities as described in Table 15-1, with at least the behavior described as mandatory in the referenced underlying specification, with the following ~~exceptions~~exceptions:

1. If any operand (except one which follows `--`) starts with a hyphen, the behavior is unspecified.

Rationale (Informative): Applications should place options before operands, or use `--`, as needed. This text is needed because, by default, GNU option parsing differs from POSIX, unless the environment variable POSIXLY_CORRECT is set. For example, **ls . -a** in GNU **ls** means to list the current directory, showing all files (that is, "`.`" is an operand and `-a` is an option). In POSIX, "`.`" and `-a` are both operands, and the command means to list the current directory, and also the file named `-a`. Suggesting that applications rely on the setting of the POSIXLY_CORRECT environment variable, or try to set it, seems worse than just asking the applictions to invoke commands in ways which work with either the POSIX or GNU behaviors.

Table 15-1 Commands And Utilities

~~[~~ [1]	~~dmesg~~ dmesg [2]	~~id~~ id [1]	~~mount~~ mount [2]	~~sort~~ sort [1]
~~ar~~ ar [2]	~~du~~ du [2]	~~install~~ install [2]	~~msgfmt~~ msgfmt [2]	~~split~~ split [1]

Referenced Specification(s)

[1]. ISO POSIX (2003)

[2]. ~~this specification~~This Specification

An LSB conforming implementation shall provide the shell built in utilities as described in Table 15-2, with at least the behavior described as mandatory in the referenced underlying specification, with the following ~~exceptions~~exceptions:

1. The built in commands and utilities shall be provided by the **sh** utility itself, and need not be implemented in a manner so that they can be accessed via the exec family of functions as defined in ISO POSIX (2003) and should not be

invoked directly by those standard utilities that execute other utilities (**env**, **find**, **nice**, **nohup**, **time**, **xargs**).

Rationale (Informative): Since the built in utilities must affect the environment of the calling process, they have no effect when executed as a file.

Table 15-2 Built In Utilities

~~cd~~ cd [1]	~~getopts~~ getopts [1]	~~read~~ read [1]	~~umask~~ umask [1]	~~wait~~ wait [1]

Referenced Specification(s)

[1]. ISO POSIX (2003)

15.2 Command Behavior

This section contains descriptions for commands and utilities whose specified behavior in the LSB contradicts or extends the standards referenced. It also contains commands and utilities only required by the LSB and not specified by other standards.

ar

Name

`ar` — create and maintain library archives (DEPRECATED)

Description

ar is deprecated from the LSB and is expected to disappear from a future version of the LSB.

Rationale: The LSB generally does not include software development utilities nor does it specify .o and .a file formats.

ar is as specified in ISO POSIX (2003) but with differences as listed below.

Differences

-T
-C

need not be accepted.

-l

has unspecified behavior.

-q

has unspecified behavior; using -r is suggested.

at

Name

`at` — examine or delete jobs for later execution

Description

at is as specified in ISO POSIX (2003) but with differences as listed below.

Differences

Options

-d

is functionally equivalent to the -r option specified in ISO POSIX (2003).

-r

need not be supported, but the '-d' option is equivalent.

-t time

need not be supported.

Optional Control Files

The implementation shall support the XSI optional behavior for access control; however the files `at.allow` and `at.deny` may reside in `/etc` rather than `/usr/lib/cron`.

awk

Name

`awk` — pattern scanning and processing language

Description

awk is as specified in ISO POSIX (2003) but with differences as listed below.

Differences

Certain aspects of internationalized regular expressions are optional; see Internationalization and Regular Expressions.

batch

Name

`batch` — schedule commands to be executed in a batch queue

Description

The specification for **batch** is as specified in ISO POSIX (2003), but with differences as listed below.

Optional Control Files

The implementation shall support the XSI optional behavior for access control; however the files `at.allow` and `at.deny` may reside in `/etc` rather than `/usr/lib/cron`.

bc

Name

`bc` — an arbitrary precision calculator language

Description

bc is as specified in ISO POSIX (2003) but with extensions as listed below.

Extensions

The bc language may be extended in an implementation defined manner. If an implementation supports extensions, it shall also support the additional options:

-s|--standard

processes exactly the POSIX **bc** language.

-w|--warn

gives warnings for extensions to POSIX bc.

chfn

Name

`chfn` — change user name and information

Synopsis

chfn [-f *full_name*] [-h *home_phone*] [user]

Description

chfn shall update the user database. An unprivileged user may only change the fields for their own account, a user with appropriate privileges may change the fields for any account.

The fields *full_name* and *home_phone* may contain any character except:

any control character
comma
colon
equal sign

If none of the options are selected, **chfn** operates in an interactive fashion. The prompts and expected input in interactive mode are unspecified and should not be relied upon.

As it is possible for the system to be configured to restrict which fields a non-privileged user is permitted to change, applications should be written to gracefully handle these situations.

Standard Options

-f full_name

sets the user's full name.

-h home_phone

sets the user's home phone number.

Future Directions

The following two options are expected to be added in a future version of the LSB:

-o office

sets the user's office room number.

-p office_phone

sets the user's office phone number.

Note that some implementations contain a "-o other" option which specifies an additional field called "other". Traditionally, this field is not subject to the constraints about legitimate characters in fields. Also, one traditionally shall have appropriate privileges to change the other field. At this point there is no consensus about whether it is desirable to specify the other field; applications may wish to avoid using it.

The "-w work_phone" field found in some implementations should be replaced by the "-p office_phone" field. The "-r room_number" field found in some implementations is the equivalent of the "-o office" option mentioned above; which one of these two options to specify will depend on implementation experience and the decision regarding the other field.

chsh

Name

chsh — change login shell

Synopsis

chsh [-s *login_shell*] [*user*]

Description

chsh changes the user login shell. This determines the name of the user's initial login command. An unprivileged user may only change the login shell for their own account, a user with appropriate privilege may change the login shell for any account specified by *user*.

Unless the user has appropriate privilege, the initial login command name shall be one of those listed in /etc/shells. The *login_shell* shall be the absolute path (i.e. it must start with '/') to an executable file. Accounts which are restricted (in an implementation-defined manner) may not change their login shell.

If the -s option is not selected, **chsh** operates in an interactive mode. The prompts and expected input in this mode are unspecified.

Standard Options

-s login_shell

sets the login shell.

col

Name

col — filter reverse line feeds from input

Description

col is as specified in SUSv2 but with differences as listed below.

Differences

The *-p* option has unspecified behavior.

Note: Although **col** is shown as legacy in SUSv2, it is not (yet) deprecated in the LSB.

cpio

Name

`cpio` — copy file archives in and out

Description

cpio is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

Some elements of the Pattern Matching Notation are optional; see Internationalization and Pattern Matching Notation.

crontab

Name

`crontab` — maintain crontab files for individual users

Synopsis

```
crontab [-u user] file crontab [-u user] {-l | -r | -e}
```

Description

crontab is as specified in ISO POSIX (2003), but with differences as listed below.

Optional Control Files

The implementation shall support the XSI optional behavior for access control; however the files `cron.allow` and `cron.deny` may reside in `/etc` rather than `/usr/lib/cron`.

cut

Name

`cut` — split a file into sections determined by context lines

Description

cut is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

-n

has unspecified behavior.

df

Name

`df` — report file system disk space usage

Description

The **df** command shall behave as specified in ISO POSIX (2003), but with differences as listed below.

Differences

Options

If the *-k* option is not specified, disk space is shown in unspecified units. If the *-P* option is specified, the size of the unit shall be printed on the header line in the format `"%4s-blocks"`. Applications should specify *-k*.

The XSI option *-t* has unspecified behavior. Applications should not specify *-t*.

> **Rationale:** The most common implementation of **df** uses the *-t* option for a different purpose (restricting output to a particular file system type), and use of *-t* is therefore non-portable.

Operand May Identify Special File

If an argument is the absolute file name of a special file containing a mounted file system, **df** shall show the space available on that file system rather than on the file system containing the special file (which is typically the root file system).

> **Note:** In ISO POSIX (2003) the XSI optional behavior permits an operand to name a special file, but appears to require the operation be performed on the file system containing the special file. A defect report has been submitted for this case.

dmesg

Name

dmesg — print or control the system message buffer

Synopsis

dmesg [-c | -n *level* | -s *bufsize*]

Description

dmesg examines or controls the system message buffer. Only a user with appropriate privileges may modify the system message buffer parameters or contents.

Standard Options

-c

If the user has appropriate privilege, clears the system message buffer contents after printing.

-n level

If the user has appropriate privilege, sets the level at which logging of messages is done to the console.

-s bufsize

uses a buffer of *bufsize* to query the system message buffer. This is 16392 by default.

du

Name

du — estimate file space usage

Description

du is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

If the *-k* option is not specified, disk space is shown in unspecified units. Applications should specify *-k*.

echo

Name

echo — write arguments to standard output

Synopsis

```
echo [string...]
```

Description

The **echo** command is as specified in ISO POSIX (2003), but with the following differences.

Implementations may support implementation-defined options to **echo**. The behavior of **echo** if any arguments contain backslashes is also implementation defined.

Application Usage

Conforming applications ~~shall~~ should not run **echo** with a first argument starting with a hyphen, or with any arguments containing backslashes; they should use **printf** in those cases.

> **Note:** The behavior specified here is similar to that specified by ISO POSIX (2003) without the XSI option. However, the LSB ~~forbids a~~strongly recommends conforming ~~application from using~~applications not use any options (even if the implementation provides them) while ISO POSIX (2003) specifies behavior if the first operand is the string *-n*.

egrep

Name

egrep — search a file with an Extended Regular Expression pattern

Description

egrep is equivalent to **grep -E**. For further details, see the specification for **grep**.

fgrep

Name

fgrep — search a file with a fixed pattern

Description

fgrep is equivalent to grep -F. For further details, see the specification for **grep**.

file

Name

`file` — determine file type

Description

file is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

The *-M*, *-h*, *-d*, and *-i* options need not be supported.

find

Name

`find` — search for files in a directory hierarchy

Description

find shall behave as specified in ISO POSIX (2003), except as described below.

Differences

Pattern Matching

Some elements of the Pattern Matching Notation are optional; see Internationalization and Pattern Matching Notation.

Option and Operand Handling

Options and operands to **find** shall behave as described in ISO POSIX (2003), except as follows:

-H

need not be supported

-L

need not be supported

-exec ... +

argument aggregation need not be supported

Rationale: The *-H* and *-L* options are not yet widely available in implementations of the **find** command, nor is argument aggregation. A future version of this specification will require these features be supported.

fuser

Name

`fuser` — identify processes using files or sockets

Description

fuser is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

The **fuser** command is a system administration utility, see Path For System Administration Utilities.

Option Differences

-c

has unspecified behavior.

-f

has unspecified behavior.

gettext

Name

`gettext` — retrieve text string from message catalog

Synopsis

```
gettext [options] [textdomain] msgid gettext -s [options] msgid...
```

Description

The **gettext** utility retrieves a translated text string corresponding to string *`msgid`* from a message object generated with **msgfmt** utility.

The message object name is derived from the optional argument *`textdomain`* if present, otherwise from the `TEXTDOMAIN` environment variable. If no domain is specified, or if a corresponding string cannot be found, **gettext** prints *`msgid`*.

Ordinarily **gettext** looks for its message object in *`dirname`*`/`*`lang`*`/LC_MESSAGES` where *`dirname`* is the implementation-defined default directory and *`lang`* is the locale name. If present, the `TEXTDOMAINDIR` environment variable replaces the *`dirname`*.

This utility interprets C escape sequences such as `\t` for tab. Use `\\` to print a backslash. To produce a message on a line of its own, either put a `\n` at the end of *`msgid`*, or use this command in conjunction with the **printf** utility.

When used with the *`-s`* option the **gettext** utility behaves like the **echo** utility, except that the message corresponding to *`msgid`* in the selected catalog provides the arguments.

Options

`-d domainname`
`--domain=domainname`

PARAMETER translated messages from domainname.

`-e`

Enable expansion of some escape sequences.

`-n`

Suppress trailing newline.

Operands

The following operands are supported:

`textdomain`

A domain name used to retrieve the messages.

`msgid`

A key to retrieve the localized message.

Environment Variables

LANGUAGE

Specifies one or more locale names.

263 `LANG`

264 Specifies locale name.

265 `LC_MESSAGES`

266 Specifies messaging locale, and if present overrides `LANG` for messages.

267 `TEXTDOMAIN`

268 Specifies the text domain name, which is identical to the message object
269 filename without `.mo` suffix.

270 `TEXTDOMAINDIR`

271 Specifies the pathname to the message catalog, and if present replaces the
272 implementation-defined default directory.

Exit Status

273 The following exit values are returned:

274 0

275 Successful completion.

276 >0

277 An error occurred.

grep

Name

278 `grep` — print lines matching a pattern

Description

279 **grep** is as specified in ISO POSIX (2003), but with differences as listed below.

LSB Differences

280 Certain aspects of regular expression matching are optional; see Internationalization
281 and Regular Expressions.

groupadd

Name

`groupadd` — create a new group

Synopsis

```
groupadd [-g gid [-o]] group
```

Description

If the caller has appropriate privilege, the **groupadd** command shall create a new group named *`group`*. The group name shall be unique in the group database. If no *`gid`* is specified, **groupadd** shall create the new group with a unique group ID.

The **groupadd** command is a system administration utility, see Path For System Administration Utilities.

Options

`-g gid [-o]`

The new group shall have group ID *`gid`*. If the *`-o`* option is not used, no other group shall have this group ID. The value of *`gid`* shall be non-negative.

groupdel

Name

`groupdel` — delete a group

Synopsis

```
groupdel group
```

Description

If the caller has sufficient privilege, the **groupdel** command shall modify the system group database, deleting the group named *`group`*. If the group named *`group`* does not exist, **groupdel** shall issue a diagnostic message and exit with a non-zero exit status.

The **groupdel** command is a system administration utility, see Path For System Administration Utilities.

groupmod

Name

`groupmod` — modify a group

Synopsis

```
groupmod [-g gid [-o]] [-n group_name] group
```

Description

If the caller has appropriate privilege, the **groupmod** command shall modify the entry in the system group database corresponding to a group named *group*.

The **groupmod** command is a system administration utility, see Path For System Administration Utilities.

Options

-g gid [-o]

Modify the group's group ID, setting it to *gid*. If the *-o* option is not used, no other group shall have this group ID. The value of *gid*shall be non-negative.

Note: Only the group ID in the database is altered; any files with group ownership set to the original group ID are unchanged by this modification.

-n group_name

changes the name of the group from *group* to *group_name*.

groups

Name

`groups` — display a group

Synopsis

```
groups [user]
```

Description

The **groups** command shall behave as **id -Gn *[user]***, as specified in ISO POSIX (2003). The optional *user* parameter will display the groups for the named user.

gunzip

Name

`gunzip` — uncompress files

Description

gunzip is equivalent to **gzip -d**. See the specification for **gzip** for further details.

gzip

Name

`gzip` — compress or expand files

Synopsis

```
gzip [-cdfhlLnNrtvV19] [-S suffix] [name...]
```

Description

The **gzip** command shall attempt to reduce the size of the named files. Whenever possible, each file is replaced by one with the extension `.gz`, while keeping the same ownership, modes, access and modification times. If no files are specified, or if a file name is `-`, the standard input is compressed to the standard output. **gzip** shall only attempt to compress regular files. In particular, it will ignore symbolic links.

When compressing, gzip uses the deflate algorithm specified in RFC 1951: DEFLATE Compressed Data Format Specification and stores the result in a file using the gzip file format specified in RFC 1952: GZIP File Format Specification.

Options

-c, --stdout, --to-stdout

writes output on standard output, leaving the original files unchanged. If there are several input files, the output consists of a sequence of independently compressed members. To obtain better compression, concatenate all input files before compressing them.

-d, --decompress, --uncompress

the name operands are compressed files, and **gzip** shall decompress them.

-f, --force

forces compression or decompression even if the file has multiple links or the corresponding file already exists, or if the compressed data is read from or written to a terminal. If the input data is not in a format recognized by **gzip**, and if the option *`--stdout`* is also given, copy the input data without change to the standard ouput: let **gzip** behave as **cat**. If *`-f`* is not given, and when not running in the background, **gzip** prompts to verify whether an existing file should be overwritten.

-l, --list

lists the compressed size, uncompressed size, ratio and uncompressed name for each compressed file. For files that are not in **gzip** format, the uncompressed size shall be given as `-1`. If the *`--verbose`* or *`-v`* option is also specified, the crc and timestamp for the uncompressed file shall also be displayed.

For decompression, **gzip** shall support at least the following compression methods:

- deflate (RFC 1951: DEFLATE Compressed Data Format Specification)
- compress (ISO POSIX (2003))

The crc shall be given as `ffffffff` for a file not in **gzip** format.

If the *--name* or *-N* option is also specified, the uncompressed name, date and time are those stored within the compressed file, if present.

If the *--quiet* or *-q* option is also specified, the title and totals lines are not displayed.

-L, --license

displays the **gzip** license and quit.

-n, --no-name

does not save the original file name and time stamp by default when compressing. (The original name is always saved if the name had to be truncated.) When decompressing, do not restore the original file name if present (remove only the gzip suffix from the compressed file name) and do not restore the original time stamp if present (copy it from the compressed file). This option is the default when decompressing.

-N, --name

always saves the original file name and time stamp when compressing; this is the default. When decompressing, restore the original file name and time stamp if present. This option is useful on systems which have a limit on file name length or when the time stamp has been lost after a file transfer.

-q, --quiet

suppresses all warnings.

-r, --recursive

travels the directory structure recursively. If any of the file names specified on the command line are directories, **gzip** will descend into the directory and compress all the files it finds there (or decompress them in the case of **gunzip**).

-S .suf, --sufix .suf

uses suffix `.suf` instead of `.gz`.

-t, --test

checks the compressed file integrity.

-v, --verbose

displays the name and percentage reduction for each file compressed or decompressed.

-#, --fast, --best

regulates the speed of compression using the specified digit #, where *-1* or *--fast* indicates the fastest compression method (less compression) and *-9* or *--best* indicates the slowest compression method (best compression). The default compression level is *-6* (that is, biased towards high compression at expense of speed).

LSB Deprecated Options

The behaviors specified in this section are expected to disappear from a future version of the LSB; applications should only use the non-LSB-deprecated behaviors.

-V, --version

displays the version number and compilation options, then quits.

hostname

Name

`hostname` — show or set the system's host name

Synopsis

```
hostname [name]
```

Description

hostname is used to either display or, with appropriate privileges, set the current host name of the system. The host name is used by many applications to identify the machine.

When called without any arguments, the program displays the name of the system as returned by the `gethostname()` function.

When called with a *name* argument, and the user has appropriate privilege, the command sets the host name.

> **Note:** It is not specified if the hostname displayed will be a fully qualified domain name. Applications requiring a particular format of hostname should check the output and take appropriate action.

install

Name

`install` — copy files and set attributes

Synopsis

```
install [option...] SOURCE DEST install [option...] SOURCE... DEST install [-d
| --directory] [option...] DIRECTORY...
```

Description

In the first two formats, copy *`SOURCE`* to *`DEST`* or multiple *`SOURCE(s)`* to the existing *`DEST`* directory, optionally setting permission modes and file ownership. In the third format, each *`DIRECTORY`* and any missing parent directories shall be created.

Standard Options

--backup[=METHOD]

makes a backup of each existing destination file. *`METHOD`* may be one of the following:

`none` or *`off`*

never make backups.

`numbered` or *`t`*

make numbered backups. A numbered backup has the form `"%s.~%d~", target_name, version_number`. Each backup shall increment the version number by 1.

`existing` or *`nil`*

behave as numbered if numbered backups exist, or simple otherwise.

`simple` or *`never`*

append a suffix to the name. The default suffix is '~', but can be overriden by setting SIMPLE_BACKUP_SUFFIX in the environment, or via the *`-S`* or *`--suffix`* option.

If no *`METHOD`* is specified, the environment variable VERSION_CONTROL shall be examined for one of the above. Unambiguous abbreviations of *`METHOD`* shall be accepted. If no *`METHOD`* is specified, or if *`METHOD`* is empty, the backup method shall default to `existing`.

If *`METHOD`* is invalid or ambiguous, **install** shall fail and issue a diagnostic message.

-b

is equivalent to *`--backup=existing`*.

-d, --directory

treats all arguments as directory names; creates all components of the specified directories.

-D

creates all leading components of DEST except the last, then copies SOURCE to DEST; useful in the 1st format.

-g GROUP, --group=GROUP

if the user has appropriate privilege, sets group ownership, instead of process' current group. *GROUP* is either a name in the user group database, or a positive integer, which shall be used as a group-id.

-m MODE, --mode=MODE

sets permission mode (specified as in **chmod**), instead of the default `rwxr-xr-x`.

-o OWNER, --owner=OWNER

if the user has appropriate privilege, sets ownership. *OWNER* is either a name in the user login database, or a positive integer, which shall be used as a user-id.

-p, --preserve-timestamps

copies the access and modification times of *SOURCE* files to corresponding destination files.

-s, --strip

strips symbol tables, only for 1st and 2nd formats.

-S SUFFIX, --suffix=SUFFIX

equivalent to *`--backup=existing`*, except if a simple suffix is required, use *SUFFIX*.

--verbose

prints the name of each directory as it is created.

-v, --verbose

print the name of each file before copying it to `stdout`.

install_initd

Name

`install_initd` — activate an init script

Synopsis

`/usr/lib/lsb/install_initd` `initd_file`

Description

install_initd shall activate a system initialization file that has been copied to an implementation defined location such that this file shall be run at the appropriate point during system initialization. The **install_initd** command is typically called in the postinstall script of a package, after the script has been copied to `/etc/init.d`. See also Installation and Removal of Init Scripts.

ipcrm

Name

`ipcrm` — remove IPC Resources

Synopsis

```
ipcrm [-q msgid | -Q msgkey | -s semid | -S semkey | -m shmid | -M shmkey]...ipcrm
[shm | msg | msg] id...
```

Description

If any of the *-q*, *-Q*, *-s*, *-S*, *-m*, *or -M* arguments are given, the **ipcrm** shall behave as described in ISO POSIX (2003).

Otherwise, **ipcrm** shall remove the resource of the specified type identified by *id*.

Future Directions

A future revision of this specification may deprecate the second synopsis form.

> **Rationale:** In its first Linux implementation, **ipcrm** used the second syntax shown in the SYNOPSIS. Functionality present in other implementations of **ipcrm** has since been added, namely the ability to delete resources by key (not just identifier), and to respect the same command line syntax. The previous syntax is still supported for backwards compatibility only.

ipcs

Name

`ipcs` — provide information on ipc facilities

Synopsis

```
ipcs [-smq] [-tcp]
```

Description

ipcs provides information on the ipc facilities for which the calling process has read access.

> **Note:** Although this command has many similarities with the optional **ipcs** utility described in ISO POSIX (2003), it has substantial differences and is therefore described separately. The options specified here have similar meaning to those in ISO POSIX (2003); other options specified there have unspecified behavior on an LSB conforming implementation. See Application Usage below. The output format is not specified.

Resource display options

-m

shared memory segments.

-q

message queues.

-s

semaphore arrays.

Output format options

-t

time.

-p

pid.

-c

creator.

Application Usage

In some implementations of ipcs the *-a* option will print all information available. In other implementations the *-a* option will print all resource types. Therefore, applications shall not use the *-a* option.

Some implementations of **ipcs** provide more output formats than are specified here. These options are not consistent between differing implementations of **ipcs**. Therefore, only the *-t*, *-c* and *-p* option formatting flags may be used. At least one of the *-t*, *-c* and *-p* options and at least one of *-m*, *-q* and *-s* options shall be specified. If no options are specified, the output is unspecified.

killall

Name

`killall` — kill processes by name

Synopsis

```
killall [-egiqvw] [-signal] name... killall -l killall -V
```

Description

killall sends a signal to all processes running any of the specified commands. If no signal name is specified, `SIGTERM` is sent.

Signals can be specified either by name (e.g. `-HUP`) or by number (e.g. `-1`). Signal `0` (check if a process exists) can only be specified by number.

If the command name contains a slash (/), processes executing that particular file will be selected for killing, independent of their name.

killall returns a non-zero return code if no process has been killed for any of the listed commands. If at least one process has been killed for each command, **killall** returns zero.

A **killall** process never kills itself (but may kill other **killall** processes).

Standard Options

-e

requires an exact match for very long names. If a command name is longer than 15 characters, the full name may be unavailable (i.e. it is swapped out). In this case, **killall** will kill everything that matches within the first 15 characters. With -e, such entries are skipped. **killall** prints a message for each skipped entry if -v is specified in addition to -e.

-g

kills the process group to which the process belongs. The kill signal is only sent once per group, even if multiple processes belonging to the same process group were found.

-i

asks interactively for confirmation before killing.

-l

lists all known signal names.

-q

does not complain if no processes were killed.

-v

reports if the signal was successfully sent.

LSB Deprecated Options

The behaviors specified in this section are expected to disappear from a future version of the LSB; applications should only use the non-LSB-deprecated behaviors.

-V

displays version information.

lpr

Name

`lpr` — off line print

Synopsis

```
lpr [-l] [-p] [-Pprinter] [-h] [-s] [-#copies] [-J name] [-T title] [name ......]
```

Description

lpr uses a spooling daemon to print the named files when facilities become available. If no names appear, the standard input is assumed.

Standard Options

-l

identifies binary data that is not to be filtered but sent as raw input to printer.

-p

formats with "pr" before sending to printer.

-Pprinter

sends output to the printer named printer instead of the default printer.

-h

suppresses header page.

-s

uses symbolic links.

-#copies

specifies copies as the number of copies to print.

-J name

specifies name as the job name for the header page.

-T title

specifies title as the title used for "pr".

ls

Name

`ls` — list directory contents

Description

ls shall behave as specified in ISO POSIX (2003), but with extensions listed below.

Extensions

-l

If the file is a character special or block special file, the size of the file shall be replaced with two unsigned numbers in the format `"%u, %u"`, representing the major and minor device numbers associated with the special file.

Note: The LSB does not specify the meaning of the major and minor devices numbers.

-p

in addition to ISO POSIX (2003) XSI optional behavior of printing a slash for a directory, **ls -p** may display other characters for other file types.

lsb_release

Name

`lsb_release` — print distribution specific information

Synopsis

```
lsb_release [OPTION...]
```

Description

The **lsb_release** command prints certain LSB (Linux Standard Base) and Distribution information.

If no options are given, the *-v* option is assumed.

Options

-v, --version

displays version of LSB against which distribution is compliant. The version is expressed as a colon separated list of LSB module descriptions. LSB module descriptions are dash separated tuples containing the module name, version, and architecture name. The output is a single line of text of the following format:

`LSB Version:\t<ListAsDescribedAbove>`

Note: An implementation may support multiple releases of the same module. Version specific library interfaces, if any, will be selected by the program interpreter, which changes from release to release. Version specific commands and utilities, if any, will be described in the relevant specification.

-i, --id

displays string id of distributor. The output is a single line of text of the following format:

`Distributor ID:\t<DistributorID>`

-d, --description

displays single line text description of distribution. The output is of the following format:

`Description:\t<Description>`

-r, --release

displays release number of distribution. The output is a single line of text of the following format:

`Release:\t<Release>`

-c, --codename

displays codename according to distribution release. The output is a single line of text of the following format.

`Codename:\t<Codename>`

-a, --all

608 displays all of the above information.

609 -s, --short

610 displays all of the above information in short output format.

611 -h, --help

612 displays a human-readable help message.

Examples

613 The following command will list the LSB Profiles which are currently supported on
614 this platform.

```
615 example% lsb_release -v
616 LSB Version:
617 core-2.03.1-ia32:core-2.03.1-noarch:graphics-2.03.1-ia32:graphics-2.
618 03.1-noarch
```

m4

Name

619 `m4` — macro processor

Description

620 **m4** is as specified in ISO POSIX (2003), but with extensions as listed below.

Extensions

621 -P

622 forces all builtins to be prefixed with `m4_`. For example, `define` becomes
623 `m4_define`.

624 -I *`directory`*

625 Add *`directory`* to the end of the search path for includes.

md5sum

Name

`md5sum` — generate or check MD5 message digests

Synopsis

```
md5sum [-c [file] | file]
```

Description

For each file, write to standard output a line containing the MD5 message digest of that file, followed by one or more blank characters, followed by the name of the file. The MD5 message digest shall be calculated according to RFC 1321: The MD5 Message-Digest Algorithm and output as 32 hexadecimal digits.

If no file names are specified as operands, read from standard input and use `"-"` as the file name in the output.

Options

-c [file]

checks the MD5 message digest of all files named in *`file`* against the message digest listed in the same file. The actual format of *`file`* is the same as the output of **md5sum**. That is, each line in the file describes a file. If *`file`* is not specified, read message digests from `stdin`.

Exit Status

md5sum shall exit with status 0 if the sum was generated successfully, or, in check mode, if the check matched. Otherwise, **md5sum** shall exit with a non-zero status.

mknod

Name

mknod — make special files

Synopsis

```
mknod [-m mode | --mode=mode] name type [major minor]mknod [--version]
```

Description

The **mknod** command shall create a special file named *name* of the given *type*.

The *type* shall be one of the following:

b

creates a block (buffered) special file with the specified *major* and *minor* device numbers.

c, u

creates a character (unbuffered) special file with the specified *major* and *minor* device numbers.

p

creates a FIFO.

Options

-m *mode*, --mode=*mode*

create the special file with file access permissions set as described in *mode*. The permissions may be any absolute value (i.e. one not containing '+' or '-') acceptable to the **chmod** command.

--version

output version information and exit.

Note: This option may be deprecated in a future release of this specification.

If *type* is p, *major* and *minor* shall not be specified. Otherwise, these parameters are mandatory.

Future Directions

This command may be deprecated in a future version of this specification. The *major* and *minor* operands are insufficently portable to be specified usefully here. Only a FIFO can be portably created by this command, and the **mkfifo** command is a simpler interface for that purpose.

mktemp

Name

`mktemp` — make temporary file name (unique)

Synopsis

```
mktemp [-q] [-u] template
```

Description

The **mktemp** command takes the given file name *`template`* and overwrites a portion of it to create a file name. This file name shall be unique and suitable for use by the application.

The *`template`* should have at least six trailing `'X'` characters. These characters are replaced with characters from the portable filename character set in order to generate a unique name.

If **mktemp** can successfully generate a unique file name, and the *`-u`* option is not present, the file shall be created with read and write permission only for the current user. The **mktemp** command shall write the filename generated to the standard output.

Options

-q

fail silently if an error occurs. Diagnostic messages to `stderr` are suppressed, but the command shall still exit with a non-zero exit status if an error occurs.

-u

operates in `unsafe' mode. A unique name is generated, but the temporary file shall be unlinked before **mktemp** exits. Use of this option is not encouraged.

more

Name

`more` — display files on a page-by-page basis

Description

more is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

The **more** command need not respect the `LINES` and `COLUMNS` environment variables.

The following additional options may be supported:

-num

specifies an integer which is the screen size (in lines).

+num

starts at line number *num*.

+/pattern

Start at the first line matching the pattern, equivalent to executing the search forward (`/`) command with the given pattern immediately after opening each file.

The following options from ISO POSIX (2003) may behave differently:

-e

has unspecified behavior.

-i

has unspecified behavior.

-n

has unspecified behavior.

-p

Either clear the whole screen before displaying any text (instead of the usual scrolling behavior), or provide the behavior specified by ISO POSIX (2003). In the latter case, the syntax is "*-p command*".

-t

has unspecified behavior.

The **more** command need not support the following interactive commands:

g
G
u
control u
control f
newline
j
k
r
R
m
' (return to mark)
/!
?
N
:e
:t
control g
ZZ

Rationale

The *+num* and *+/string* options are deprecated in SUSv2, and have been removed in ISO POSIX (2003); however this specification continues to specify them because the publicly available `util-linux` package does not support the replacement (-p *command*). The *+command* option as found in SUSv2 is more general than is specified here, but the `util-linux` package appears to only support the more specific *+num* and *+/string* forms.

mount

Name

`mount` — mount a file system

Synopsis

```
mount [-hV]mount [-a] [-fFnrsvw] [-t vfstype]mount [-fnrsvw] [-o options [,...]]
[device | dir]mount [-fnrsvw] [-t vfstype] [-o options] device dir
```

Description

As described in ISO POSIX (2003), all files in the system are organized in a directed graph, known as the file hierarchy, rooted at `/`. These files can be spread out over several underlying devices. The **mount** command shall attach the file system found on some underlying device to the file hierarchy.

Options

-v

invoke verbose mode. The **mount** command shall provide diagnostic messages on `stdout`.

-a

mount all file systems (of the given types) mentioned in `/etc/fstab`.

-F

If the *-a* option is also present, fork a new incarnation of **mount** for each device to be mounted. This will do the mounts on different devices or different NFS servers in parallel.

-f

cause everything to be done except for the actual system call; if it's not obvious, this `fakes' mounting the file system.

-n

mount without writing in `/etc/mtab`. This is necessary for example when `/etc` is on a read-only file system.

-s

ignore **mount** options not supported by a file system type. Not all file systems support this option.

-r

mount the file system read-only. A synonym is *-o ro*.

-w

mount the file system read/write. (default) A synonym is *-o rw*.

-L label

747 If the file `/proc/partitions` is supported, mount the partition that has the
748 specified label.

749 -U uuid

750 If the file `/proc/partitions` is supported, mount the partition that has the
751 specified uuid.

752 -t vfstype

753 indicate a file system type of *`vfstype`*.

754 More than one type may be specified in a comma separated list. The list of file
755 system types can be prefixed with `no` to specify the file system types on which
756 no action should be taken.

757 -o

758 options are specified with a *`-o`* flag followed by a comma-separated string of
759 options. Some of these options are only useful when they appear in the
760 `/etc/fstab` file. The following options apply to any file system that is being
761 mounted:

762 async

763 perform all I/O to the file system asynchronously.

764 atime

765 update inode access time for each access. (default)

766 auto

767 in `/etc/fstab`, indicate the device is mountable with *`-a`*.

768 defaults

769 use default options: `rw`, `suid`, `dev`, `exec`, `auto`, `nouser`, `async`.

770 dev

771 interpret character or block special devices on the file system.

772 exec

773 permit execution of binaries.

774 noatime

775 do not update file access times on this file system.

776 noauto

777 in `/etc/fstab`, indicates the device is only explicitly mountable.

778 nodev

779 do not interpret character or block special devices on the file system.

780 noexec

781 do not allow execution of any binaries on the mounted file system.

782 nosuid

783 do not allow set-user-identifier or set-group-identifier bits to take effect.

784 nouser

785 forbid an unprivileged user to mount the file system. (default)

786 remount

787 remount an already-mounted file system. This is commonly used to change
788 the mount options for a file system, especially to make a read-only file
789 system writable.

790 ro

791 mount the file system read-only.

792 rw

793 mount the file system read-write.

794 suid

795 allow set-user-identifier or set-group-identifier bits to take effect.

796 sync

797 do all I/O to the file system synchronously.

798 user

799 allow an unprivilieged user to mount the file system. This option implies
800 the options `noexec`, `nosuid`, `nodev` unless overridden by subsequent
801 options.

LSB Deprecated Options

802 The behaviors specified in this section are expected to disappear from a future
803 version of the LSB; applications should only use the non-LSB-deprecated behaviors.

804 -V

805 output version and exit.

msgfmt

Name

`msgfmt` — create a message object from a message file

Synopsis

`msgfmt` `[options...]` *`filename`*`...`

Description

The **msgfmt** command generates a binary message catalog from a textual translation description. Message catalogs, or message object files, are stored in files with a `.mo` extension.

> **Note:** The format of message object files is not guaranteed to be portable. Message catalogs should always be generated on the target architecture using the **msgfmt** command.

The source message files, otherwise known as portable object files, have a `.po` extension.

The *`filename`* operands shall be portable object files. The `.po` file contains messages to be displayed to users by system utilities or by application programs. The portable object files are text files, and the messages in them can be rewritten in any language supported by the system.

If any *`filename`* is `-`, a portable object file shall be read from the standard input.

The **msgfmt** command interprets data as characters according to the current setting of the `LC_CTYPE` locale category.

Options

-c
--check

Detect and diagnose input file anomalies which might represent translation errors. The `msgid` and `msgstr` strings are studied and compared. It is considered abnormal that one string starts or ends with a newline while the other does not.

If the message is flagged as `c-format` (see Comment Handling), check that the `msgid` string and the `msgstr` translation have the same number of `%` format specifiers, with matching types.

-D *`directory`*
--directory=*`directory`*

Add directory to list for input files search. If *`filename`* is not an absolute pathname and *`filename`* cannot be opened, search for it in *`directory`*. This option may be repeated. Directories shall be searched in order, with the leftmost *`directory`* searched first.

-f
--use-fuzzy

Use entries marked as `fuzzy` in output. If this option is not specified, such entries are not included into the output. See Comment Handling below.

842 -o *output-file*
843 --output-file=*output-file*

844 Specify the output file name as `output-file`. If multiple domains or duplicate
845 msgids in the `.po` file are present, the behavior is unspecified. If output-file is `-`,
846 output is written to standard output.

847 --strict

848 Ensure that all output files have a `.mo` extension. Output files are named either
849 by the *-o* (or *--output-file*) option, or by domains found in the input files.

850 -v
851 --verbose

852 Print additional information to the standard error, including the number of
853 translated strings processed.

Operands

854 The *filename* operands are treated as portable object files. The format of portable
855 object files is defined in EXTENDED DESCRIPTION.

Standard Input

856 The standard input is not used unless a *filename* operand is specified as "-".

Environment Variables

857 LANGUAGE

858 Specifies one or more locale names.

859 LANG

860 Specifies locale name.

861 LC_ALL

862 Specifies locale name for all categories. If defined, overrides LANG, LC_CTYPE
863 and LC_MESSAGES.

864 LC_CTYPE

865 Determine the locale for the interpretation of sequences of bytes of text data as
866 characters (for example, single-byte as opposed to multi-byte characters in
867 arguments and input files).

868 LC_MESSAGES

869 Specifies messaging locale, and if present overrides LANG for messages.

Standard Output

870 The standard output is not used unless the option-argument of the *-o* option is
871 specified as `-`.

Extended Description

The format of portable object files (`.po` files) is defined as follows. Each `.po` file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a hash mark (#) and end with the newline character. Empty lines, or lines containing only white-space, shall be ignored. Comments can in certain circumstances alter the behavior of **msgfmt**. See Comment Handling below for details on comment processing. The format of a statement is:

```
directive value
```

Each `directive` starts at the beginning of the line and is separated from `value` by white space (such as one or more space or tab characters). The `value` consists of one or more quoted strings separated by white space. If two or more strings are specified as `value`, they are normalized into single string using the string normalization syntax specified in ISO C (1999). The following directives are supported:

```
domain domainname
```

```
msgid message_identifier
```

```
msgid_plural untranslated_string_plural
```

```
msgstr message_string
```

```
msgstr[n] message_string
```

The behavior of the `domain` directive is affected by the options used. See OPTIONS for the behavior when the *`-o`* option is specified. If the *`-o`* option is not specified, the behavior of the `domain` directive is as follows:

1. All msgids from the beginning of each `.po` file to the first `domain` directive are put into a default message object file, messages (or `messages.mo` if the *`--strict`* option is specified).
2. When **msgfmt** encounters a `domain domainname` directive in the `.po` file, all following *`msgids`* until the next `domain` directive are put into the message object file `domainname` (or `domainname.mo` if *`--strict`* option is specified).
3. Duplicate *`msgids`* are defined in the scope of each domain. That is, a *`msgid`* is considered a duplicate only if the identical *`msgid`* exists in the same domain.
4. All duplicate *`msgids`* are ignored.

The `msgid` directive specifies the value of a message identifier associated with the directive that follows it. The `msgid_plural` directive specifies the plural form message specified to the plural message handling functions `ngettext()`, `dngettext()` or `dcngettext()`. The message_identifier string identifies a target string to be used at retrieval time. Each statement containing a `msgid` directive shall be followed by a statement containing a `msgstr` directive or `msgstr[n]` directives.

The `msgstr` directive specifies the target string associated with the *`message_identifier`* string declared in the immediately preceding `msgid` directive.

The `msgstr[`*`n`*`]` (where *n* = 0, 1, 2, ...) directive specifies the target string to be used with plural form handling functions `ngettext()`, `dngettext()` and `dcngettext()`.

Message strings can contain the following escape sequences:

Table 15-1 Escape Sequences

`\n`	newline
`\t`	tab
`\v`	vertical tab

\b	backspace
\r	carriage return
\f	formfeed
\\	backslash
\"	double quote
\ddd	octal bit pattern
\xHH	hexadecimal bit pattern

Comment Handling

Comments are introduced by a #, and continue to the end of the line. The second character (i.e. the character following the #) has special meaning. Regular comments should follow a space character. Other comment types include:

```
# normal-comments
#. automatic-comments
#: reference...
#, flag
```

Automatic and reference comments are typically generated by external utilities, and are not specified by the LSB. The **msgfmt** command shall ignore such comments.

> **Note:** Portable object files may be produced by unspecified tools. Some of the comment types described here may arise from the use of such tools. It is beyond the scope of this specification to describe these tools.

The `#,` comments require one or more flags separated by the comma (`,`) character. The following flags can be specified:

fuzzy

> This flag shows that the following `msgstr` string might not be a correct translation. Only the translator (i.e. the individual undertaking the translation) can judge if the translation requires further modification, or is acceptable as is. Once satisfied with the translation, the translator then removes this fuzzy flag.
>
> If this flag is specified, the **msgfmt** utility will not generate the entry for the immediately following `msgid` in the output message catalog, unless the *`--use-fuzzy`* is specified.

c-format
no-c-format

> The `c-format` flag indicates that the `msgid` string is used as format string by `printf()`-like functions. If the `c-format` flag is given for a string the **msgfmt** utility may perform additional tests to check the validity of the translation.

Plurals

The msgid entry with empty string ("") is called the header entry and is treated specially. If the message string for the header entry contains `nplurals=value`, the value indicates the number of plural forms. For example, if `nplurals=4`, there are 4 plural forms. If `nplurals` is defined, there should be a `plural=expression` on the same line, separated by a semicolon (;) character. The expression is a C language expression to determine which version of `msgstr[n]` to be used based on the value of `n`, the last argument of `ngettext()`, `dngettext()` or `dcngettext()`. For example:

```
nplurals=2; plural=n == 1 ? 0 : 1
```

indicates that there are 2 plural forms in the language; `msgstr[0]` is used if `n == 1`, otherwise `msgstr[1]` is used. Another example:

```
nplurals=3; plural=n==1 ? 0 : n==2 ? 1 : 2
```

indicates that there are 3 plural forms in the language; `msgstr[0]` is used if `n == 1`, `msgstr[1]` is used if `n == 2`, otherwise `msgstr[2]` is used.

If the header entry contains `charset=`*`codeset`* string, the *`codeset`* is used to indicate the codeset to be used to encode the message strings. If the output string's codeset is different from the message string's codeset, codeset conversion from the message strings's codeset to the output string's codeset will be performed upon the call of `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, and `dcngettext()`. The output string's codeset is determined by the current locale's codeset (the return value of nl_langinfo(CODESET)) by default, and can be changed by the call of `bind_textdomain_codeset()`.

Exit Status

The following exit values are returned:

0

Successful completion.

>0

An error occurred.

Application Usage

Neither **msgfmt** nor any `gettext()` function imposes a limit on the total length of a message. Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.

Examples

Example 1: Examples of creating message objects from message files.

In this example `module1.po`, `module2.po` and `module3.po` are portable message object files.

```
example% cat module1.po

# default domain "messages"

msgid "message one"

msgstr "mensaje número uno"

```

```
#

domain "help_domain"

msgid "help two"

msgstr "ayuda número dos"

#

domain "error_domain"

msgid "error three"

msgstr "error número tres"

example% cat module2.po

# default domain "messages"

msgid "message four"

msgstr "mensaje número cuatro"

#

domain "error_domain"

msgid "error five"

msgstr "error número cinco"

#

domain "window_domain"

msgid "window six"

msgstr "ventana número seises"

example% cat module3.po

# default domain "messages"

msgid "message seven"

msgstr "mensaje número siete"
```

The following command will produce the output files `messages`, `help_domain`, and `error_domain`.

```
example% msgfmt module1.po
```

The following command will produce the output files `messages.mo`, `help_domain.mo`, `error_domain.mo`, and `window_domain.mo`.

```
example% msgfmt module1.po module2.po
```

The following example will produce the output file `hello.mo`.

```
example% msgfmt -o hello.mo module3.po
```

newgrp

Name

`newgrp` — change group ID

Synopsis

```
newgrp [group]
```

Description

The **newgrp** command is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

The *-l* option specified in ISO POSIX (2003) need not be supported.

od

Name

od — dump files in octal and other formats

Synopsis

```
od [-abcdfilox] [-w width | --width-width] [-v] [-A address_base] [-j skip] [-n count]
[-t type_string] [file...]od --traditional [options] [file] [[+]offset [.] [b]]
[[+]label [.] [b]]
```

Description

The **od** command shall provide all of the madatory functionality specified in ISO POSIX (2003), but with extensions and differences to the XSI optional behavior as listed below.

Extensions and Differences

-s

unspecified behavior.

Note: Applications wishing to achieve the ISO POSIX (2003) behavior for *-s* should instead use *-t d2*.

-w*width*, --width[=*width*]

each output line is limited to *width* bytes from the input.

--traditional

accepts arguments in traditional form, see Traditional Usage below.

Note: The XSI optional behavior for offset handling described in ISO POSIX (2003) is not supported unless the *--traditional* option is also specified.

Pre-POSIX and XSI Specifications

The LSB supports mixing options between the mandatory and XSI optional synopsis forms in ISO POSIX (2003). The LSB shall support the following options:

-a

is equivalent to *-t a*, selects named characters.

-b

is equivalent to *-t o1*, selects octal bytes.

-c

is equivalent to *-t c*, selects characters.

-d

is equivalent to *-t u2*, selects unsigned decimal two byte units.

-f

is equivalent to *-t fF*, selects floats.

-i

is equivalent to `-t d2`, selects decimal two byte units.

Note: This usage may change in future releases; portable applications should use `-t d2`.

-l

is equivalent to `-t d4`, selects decimal longs.

-o

is equivalent to `-t o2`, selects octal two byte units.

-x

is equivalent to `-t x2`, selects hexadecimal two byte units.

Note that the XSI option `-s` need not be supported.

Traditional Usage

If the `--traditional` option is specified, there may be between zero and three operands specified.

If no operands are specified, then **od** shall read the standard input.

If there is exactly one operand, and it is an offset of the form `[+]offset[.][b]`, then it shall be interpreted as specified in ISO POSIX (2003). The file to be dumped shall be the standard input.

If there are exactly two operands, and they are both of the form `[+]offset[.][b]`, then the first shall be treated as an offset (as above), and the second shall be a label, in the same format as the offset. If a label is specified, then the first output line produced for each input block shall be preceded by the input offset, cumulative across input files, of the next byte to be written, followed by the label, in parentheses. The label shall increment in the same manner as the offset.

If there are three operands, then the first shall be the file to dump, the second the offset, and the third the label.

Note: Recent versions of **coreutils** contain an **od** utility that conforms to ISO POSIX (2003). However, in April 2005, this version was not in widespread use. A future version of this specification may remove the differences.

passwd

Name

`passwd` — change user password

Synopsis

```
passwd [-x max] [-n min] [-w warn] [-i inact] name passwd {-l | -u} name
```

Description

passwd changes authentication information for user and group accounts, including passwords and password expiry details, and may be used to enable and disable accounts. Only a user with appropriate privilege may change the password for other users or modify the expiry information.

Options

-x max

sets the maximum number of days a password remains valid.

-n min

sets the minimum number of days before a password may be changed.

-w warn

sets the number of days warning the user will receive before their password will expire.

-i inactive

disables an account after the password has been expired for the given number of days.

-l

disables an account by changing the password to a value which matches no possible encrypted value.

-u

re-enables an account by changing the password back to its previous value.

patch

Name

`patch` — apply a diff file to an original

Description

patch is as specified in ISO POSIX (2003), but with extensions as listed below.

Extensions

--binary

reads and write all files in binary mode, except for standard output and /dev/tty. This option has no effect on POSIX-compliant systems.

-u, --unified

interprets the patch file as a unified context diff.

pidof

Name

`pidof` — find the process ID of a running program

Synopsis

```
pidof [-s] [-x] [-o omitpid...] program...
```

Description

Return the process ID of a process which is running the program named on the command line.

The **pidof** command is a system administration utility, see Path For System Administration Utilities.

Options

-s

instructs the program to only return one pid.

-x

causes the program to also return process id's of shells running the named scripts.

-o

omits processes with specified process id.

remove_initd

Name

remove_initd — clean up init script system modifications introduced by install_initd

Synopsis

```
/usr/lib/lsb/remove_initd initd_file
```

Description

remove_initd processes the removal of the modifications made to a distribution's init script system by the **install_initd** program. This cleanup is performed in the preuninstall script of a package; however, the package manager is still responsible for removing the script from the repository. See also Installation and Removal of Init Scripts.

renice

Name

renice — alter priority of running processes

Description

renice is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

-n increment

has unspecified behavior.

sed

Name

sed — stream editor

Description

sed is as specified in ISO POSIX (2003), but with differences as listed below.

LSB Differences

Certain aspects of internationalized regular expressions are optional; see Internationalization and Regular Expressions.

sendmail

Name

`sendmail` — an electronic mail transport agent

Synopsis

```
/usr/sbin/sendmail [options] [address...]
```

Description

To deliver electronic mail (email), applications shall support the interface provided by **sendmail** (described here). This interface shall be the default delivery method for applications.

This program sends an email message to one or more recipients, routing the message as necessary. This program is not intended as a user interface routine.

With no options, **sendmail** reads its standard input up to an end-of-file or a line consisting only of a single dot and sends a copy of the message found there to all of the addresses listed. It determines the network(s) to use based on the syntax and contents of the addresses.

If an address is preceded by a backslash, `'\'`, it is unspecified if the address is subject to local alias expansion.

The format of messages shall be as defined in RFC 2822:Internet Message Format.

> **Note:** The name **sendmail** was chosen for historical reasons, but the **sendmail** command specified here is intended to reflect functionality provided by **smail**, **exim** and other implementations, not just the **sendmail** implementation.

Options

-bm

read mail from standard input and deliver it to the recipient addresses. This is the default mode of operation.

-bp

If the user has sufficient privilege, list information about messages currently in the mail queue.

-bs

use the SMTP protocol as described in RFC 2821:Simple Mail Transfer Protocol; read SMTP commands on standard input and write SMTP responses on standard output.

In this mode, **sendmail** shall accept `\r\n` (CR-LF), as required by RFC 2821:Simple Mail Transfer Protocol, and `\n` (LF) line terminators.

-F fullname

explicitly set the full name of the sender for incoming mail unless the message already contains a `From:` message header.

If the user running **sendmail** is not sufficiently trusted, then the actual sender may be indicated in the message, depending on the configuration of the agent.

1193 -f name

1194 1195 explicitly set the envelope sender address for incoming mail. If there is no `From:` header, the address specified in the `From:` header will also be set.

1196 1197 If the user running **sendmail** is not sufficiently trusted, then the actual sender shall be indicated in the message.

1198 -i

1199 1200 1201 ignore dots alone on lines by themselves in incoming messages. If this options is not specified, a line consisting of a single dot shall terminate the input. If -bs is also used, the behavior is unspecified.

1202 -odb

1203 deliver any mail in background, if supported; otherwise ignored.

1204 -odf

1205 deliver any mail in foreground, if supported; otherwise ignored.

1206 -oem or -em

1207 mail errors back to the sender. (default)

1208 -oep or -ep

1209 write errors to the standard error output.

1210 -oeq or -eq

1211 1212 do not send notification of errors to the sender. This only works for mail delivered locally.

1213 -oi

1214 is equivalent to -i.

1215 -om

1216 1217 indicate that the sender of a message should receive a copy of the message if the sender appears in an alias expansion. Ignored if aliases are not supported.

1218 -t

1219 1220 1221 1222 1223 read the message to obtain recipients from the `To:`, `Cc:`, and `Bcc:` headers in the message instead of from the command arguments. If a `Bcc:` header is present, it is removed from the message unless there is no `To:` or `Cc:` header, in which case a `Bcc:` header with no data is created, in accordance with RFC 2822:Internet Message Format.

1224 If there are any operands, the recipients list is unspecified.

1225 This option may be ignored when not in *`-bm`* mode (the default).

1226 1227 **Note:** It is recommended that applications use as few options as necessary, none if possible.

Exit status

1228 0

successful completion on all addresses. This does not indicate successful delivery.

>0

there was an error.

~~Notes/Rationale~~

~~The **sendmail** command specified here is intended to reflect functionality provided by **smail, exim** and other implementations, not just the **sendmail** implementation.~~

sh

Name

`sh` — shell, the standard command language interpreter

Description

The **sh** utility shall behave as specified in ISO POSIX (2003), but with extensions listed below.

Shell Invocation

The shell shall support an additional option, `-l` (the letter *ell*). If the `-l` option is specified, or if the first character of argument zero (the command name) is a `'-'`, this invokation of the shell is a *login shell*.

An interactive shell, as specified in ISO POSIX (2003), that is also a login shell, or any shell if invoked with the `-l` option, shall, prior to reading from the input file, first read and execute commands from the file `/etc/profile`, if that file exists, and then from a file called `~/.profile`, if such a file exists.

> **Note:** This specification requires that the **sh** utility shall also read and execute commands in its current execution environment from all the shell scripts in the directory `/etc/profile.d`. Such scripts are read and executed as a part of reading and executing `/etc/profile`.

shutdown

Name

`shutdown` — shut the system down

Synopsis

```
/sbin/shutdown [-t sec] [-h | -r] [-akfF] time [warning-message]/sbin/shutdown
-c [warning-message]
```

Description

The **shutdown** command shall shut the system down in a secure way (first synopsis), or cancel a pending shutdown (second synopsis). When the shutdown is initiated, all logged-in users shall be notified immediately that the system is going down, and users shall be prevented from logging in to the system. The *time* specifies when the actual shutdown shall commence. See below for details. At the specified time all processes are first notified that the system is going down by the signal `SIGTERM`. After an interval (see `-t`) all processes shall be sent the signal `SIGKILL`. If neither the `-h` or the `-r` argument is specified, then the default behavior shall be to take the system to a runlevel where administrative tasks can be run. See also Run Levels.

Note: This is sometimes referred to as "single user mode".

The `-h` and `-r` options are mutually exclusive. If either the `-h` or `-r` options are specified, the system shall be halted or rebooted respectively.

Standard Options

-a

use access control. See below.

-t sec

tell the system to wait *sec* seconds between sending processes the warning and the kill signal, before changing to another runlevel. The default period is unspecified.

-k

do not really shutdown; only send the warning messages to everybody.

-r

reboot after shutdown.

-h

halt after shutdown. Actions after halting are unspecified (e.g. power off).

-f

advise the system to skip file system consistency checks on reboot.

-F

advise the system to force file system consistency checks on reboot.

-c

cancel an already running **shutdown**.

time

specify when to shut down.

The time argument shall have the following format: `[now | [+]mins | hh:mm]` If the format is `hh:mm`, `hh` shall specify the hour (1 or 2 digits) and `mm` is the minute of the hour (exactly two digits), and the shutdown shall commence at the next occurence of the specified time. If the format is `mins` (or `+mins`), where `mins` is a decimal number, shutdown shall commence in the specified number of minutes. The word `now` is an alias for `+0`.

warning-message

specify a message to send to all users.

Access Control

If the **shutdown** utility is invoked with the *-a* option, it shall check that an authorized user is currently logged in on the system console. Authorized users are listed, one per line, in the file `/etc/shutdown.allow`. Lines in this file that begin with a `'#'` or are blank shall be ignored.

Note: The intent of this scheme is to allow a keyboard sequence entered on the system console (e.g. `CTRL-ALT-DEL`, or `STOP-A`) to automatically invoke **shutdown -a**, and can be used to prevent unauthorized users from shutting the system down in this fashion.

su

Name

su — change user ID ~~or become super-user~~

Synopsis

```
su [options] [-] [username [ARGS]]
```

Description

~~**su** is used to become another user during a login session. Invoked without a username, **su** defaults to becoming the super user. The optional argument - may be used to provide an environment similar to what the user would expect had the user logged in directly.~~

~~The user will be prompted for a password, if appropriate. Invalid passwords will produce an error message. All attempts, both valid and invalid, are logged to detect abuses of the system. Applications may not assume the format of prompts and anticipated input for user interaction, because they are unspecified.~~

~~An optional command can be executed. This is done by the shell specified in /etc/passwd for the target user unless the -s or -m options are used. Any arguments supplied after the username will be passed to the invoked shell (shell shall support the -c command line option in order for a command to be passed to it).~~

~~The current environment is passed to the new shell. The value of PATHis reset to /bin:/usr/bin for unprivileged users, or /sbin:/bin:/usr/sbin:/usr/bin for users with appropriate privilege. This may be changed with the ENV_PATH and ENV_SUPATH definitions in /etc/login.defs. When using the -m or -p options, the user's environment is not changed.~~

~~A subsystem login is indicated by the presence of a "*" as the first character of the login shell. If this character is present, it shall be removed, and the remaining path (or /bin/sh if the remaining path is empty) shall be executed after changing the root directory to the directory specified as the home directory.~~

The **su** command shall start a shell running with the real and effective user and group IDs of the user *username*. If *username* is not specified, **su** shall default to an unspecified user with all appropriate privileges. If the *-s* or *--shell* is not specified, the shell to be invoked shall be that specified for *username* in the user database (see getpwnam()), or /bin/sh if there is no shell specified in the user database.

If the - option is specified, or if the first operand is -, the environment for the shell shall be initialized as if the new shell was a login shell (see Shell Invocation).

If the invoking user does not have appropriate privileges, the **su** command shall prompt for a password and validate this before continuing. Invalid passwords shall produce an error message. The **su** command shall log in an unspecified manner all invokations, whether successful or unsuccessful.

Any operands specified after the *username* shall be passed to the invoked shell.

If the option - is not specified, and if the first operand is not -, the environemnt for the new shell shall be intialized from the current environment. If none of the *-m*, *-p*, or *--preserve-environment* options are specified, the environment may be modified in unspecified ways before invoking the shell. If any of the *-m*, *-p*, or *--preserve-environment* options are specified, the environment shall not be altered.

Note: Although the **su** command shall not alter the environment, the invoked shell may still alter it before it is ready to intepret any commands.

Standard Options

-

~~makes this~~the invoked shell shall be a login shell.

-c~~, comand=~~ *command*

~~passes~~, --command ~~to the invoked shell. It is passed directly to=~~*command*

Invoke the ~~invoked~~ shell ~~(using~~with the ~~shell's -c~~ option~~), so its syntax is whatever that shell can accept~~ `-c` *command*.

-m, -p, --preserve-environment

~~does not reset~~The current environment ~~variables, and keeps~~shall be passed to the ~~same~~invoked shell ~~if it~~. If the environment variable SHELL is ~~present in /etc/shells.~~

~~-s,~~ set, it shall specify the shell~~=~~ to invoke, if it matches an entry in `/etc/shells`. If there is no matching entry in `/etc/shells`, this option shall be ignored if the `-` option is also specified, or if the first operand is `-`.

-s *shell*

~~uses~~, --shell ~~instead of the default in /etc/passwd=~~*shell*

Invoke *shell* as the comamnd interpreter. The shell specified shall be present in `/etc/shells`.

sync

Name

`sync` — flush file system buffers

Synopsis

sync

Description

Force changed blocks to disk, update the super block.

tar

Name

`tar` — file archiver

Description

tar is as specified in SUSv2, but with differences as listed below.

Differences

Some elements of the Pattern Matching Notation are optional; see Internationalization and Pattern Matching Notation.

-h

doesn't dump symlinks; dumps the files they point to.

-z

filters the archive through **gzip**.

umount

Name

umount — unmount file systems

Synopsis

```
umount [-hV]umount -a [-nrv] [-t vfstype]umount [-nrv] device | dir
```

Description

umount detaches the file system(s) mentioned from the file hierarchy. A file system is specified by giving the directory where it has been mounted.

Standard Options

-v

invokes verbose mode.

-n

unmounts without writing in /etc/mtab.

-r

tries to remount read-only if unmounting fails.

-a

unmounts all of the file systems described in /etc/mtab except for the proc file system.

-t vfstype

indicates that the actions should only be taken on file systems of the specified type. More than one type may be specified in a comma separated list. The list of file system types can be prefixed with no to specify the file system types on which no action should be taken.

-f

forces unmount (in case of an unreachable NFS system).

LSB Deprecated Options

The behaviors specified in this section are expected to disappear from a future version of the LSB; applications should only use the non-LSB-deprecated behaviors.

-V

print version and exits.

useradd

Name

`useradd` — create a new user or update default new user information

Synopsis

```
useradd [-c comment] [-d home_dir] [-g initial_group] [-G group...] [-m [-k
skeleton_dir]] [-p passwd] [-r] [-s shell] [-u uid [-o]] login useradd -D [-g
default_group] [-b default_home] [-s default_shell]
```

Description

When invoked without the *-D* option, and with appropriate privilege, **useradd** creates a new user account using the values specified on the command line and the default values from the system. The new user account will be entered into the system files as needed, the home directory will be created, and initial files copied, depending on the command line options.

When invoked with the *-D* option, **useradd** will either display the current default values, or, with appropriate privilege, update the default values from the command line. If no options are specified, **useradd** displays the current default values.

The **useradd** command is a system administration utility, see Path For System Administration Utilities.

Standard Options

-c comment

specifies the new user's password file comment field value.

-d home_dir

creates the new user using home_dir as the value for the user's login directory. The default is to append the login name to default_home and use that as the login directory name.

-g initial_group

specifies the group name or number of the user's initial login group. The group name shall exist. A group number shall refer to an already existing group. If *-g* is not specified, the implementation will follow the normal user default for that system. This may create a new group or choose a default group that normal users are placed in. Applications which require control of the groups into which a user is placed should specify *-g*.

-G group[,...]

specifies a list of supplementary groups which the user is also a member of. Each group is separated from the next by a comma, with no intervening whitespace. The groups are subject to the same restrictions as the group given with the *-g* option. The default is for the user to belong only to the initial group.

-m [-k skeleton_dir]

specifies the user's home directory will be created if it does not exist. The files contained in `skeleton_dir` will be copied to the home directory if the *`-k`* option is used, otherwise the files contained in `/etc/skel` will be used instead. Any directories contained in `skeleton_dir` or `/etc/skel` will be created in the user's home directory as well. The *`-k`* option is only valid in conjunction with the *`-m`* option. The default is to not create the directory and to not copy any files.

-p passwd

is the encrypted password, as returned by `crypt()`. The default is to disable the account.

-r

creates a system account, that is, a user with a User ID in the range reserved for system account users. If there is not a User ID free in the reserved range the command will fail.

-s shell

specifies the name of the user's login shell. The default is to leave this field blank, which causes the system to select the default login shell.

-u uid [-o]

specifies the numerical value of the user's ID. This value shall be unique, unless the *`-o`* option is used. The value shall be non-negative. The default is the smallest ID value greater than 499 which is not yet used.

Change Default Options

-b default_home

specifies the initial path prefix for a new user's home directory. The user's name will be affixed to the end of default_home to create the new directory name if the -d option is not used when creating a new account.

-g default_group

specifies the group name or ID for a new user's initial group. The named group shall exist, and a numerical group ID shall have an existing entry.

-s default_shell

specifies the name of the new user's login shell. The named program will be used for all future new user accounts.

-c comment

specifies the new user's password file comment field value.

Application Usage

The *`-D`* option will typically be used by system administration packages. Most applications should not change defaults which will affect other applications and users.

userdel

Name

`userdel` — delete a user account and related files

Synopsis

```
userdel [-r] login
```

Description

Delete the user account named *`login`*. If there is also a group named *`login`*, this command may delete the group as well, or may leave it alone.

The **userdel** command is a system administration utility, see Path For System Administration Utilities.

Options

-r

removes files in the user's home directory along with the home directory itself. Files located in other file system will have to be searched for and deleted manually.

usermod

Name

`usermod` — modify a user account

Synopsis

```
usermod [-c comment] [-d home_dir [ -m]] [-g initial_group] [-G group [,...]] [-l
login_name] [-p passwd] [-s shell] [-u uid [ -o]] login
```

Description

The **usermod** command shall modify an entry in the user account database.

The **usermod** command is a system administration utility, see Path For System Administration Utilities.

Options

-c comment

specifies the new value of the user's password file comment field.

-d home_dir

specifies the user's new login directory. If the -m option is given the contents of the current home directory will be moved to the new home directory, which is created if it does not already exist.

-g initial_group

specifies the group name or number of the user's new initial login group. The group name shall exist. A group number shall refer to an already existing group.

-G group,[...]

specifies a list of supplementary groups which the user is also a member of. Each group is separated from the next by a comma, with no intervening whitespace. The groups are subject to the same restrictions as the group given with the -g option. If the user is currently a member of a group which is not listed, the user will be removed from the group.

-l login_name

changes the name of the user from login to login_name. Nothing else is changed. In particular, the user's home directory name should probably be changed to reflect the new login name.

-p passwd

is the encrypted password, as returned by crypt(3).

-s shell

specifies the name of the user's new login shell. Setting this field to blank causes the system to select the default login shell.

-u uid [-o]

specifies the numerical value of the user's ID. This value shall be unique, unless the -o option is used. The value shall be non-negative. Any files which the user owns and which are located in the directory tree rooted at the user's home directory will have the file user ID changed automatically. Files outside of the user's home directory shall be altered manually.

xargs

Name

`xargs` — build and execute command lines from standard input

Description

xargs is as specified in ISO POSIX (2003), but with differences as listed below.

Differences

-E

has unspecified behavior.

-I

has unspecified behavior.

-L

has unspecified behavior.

Note: These options have been implemented in **findutils-4.2.9**, but this version of the utilities is not in widespread use as of April 2005. However, future versions of this specification will require support for these arguments.

1

VI Execution Environment

16 File System Hierarchy

An LSB conforming implementation shall provide the mandatory portions of the file system hierarchy specified in the Filesystem Hierarchy Standard (FHS), together with any additional requirements made in this specification.

An LSB conforming application shall conform to the Filesystem Hierarchy Standard.

The FHS allows many components or subsystems to be optional. An application shall check for the existence of an optional component before using it, and should behave in a reasonable manner if the optional component is not present.

The FHS requirement to locate the operating system kernel in either `/` or `/boot` does not apply if the operating system kernel does not exist as a file in the file system.

The FHS specifies certain behaviors for a variety of commands if they are present (for example, **ping** or **python**). However, LSB conforming applications shall not rely on any commands beyond those specified by the LSB. The mere existence of a command may not be used as an indication that the command behaves in any particular way.

The following directories or links need not be present: `/etc/X11` `/usr/bin/X11` `/usr/lib/X11` `/proc`

16.1 `/dev`: Device Files

The following shall exist under `/dev`. Other devices may also exist in `/dev`. Device names may exist as symbolic links to other device nodes located in `/dev` or subdirectories of `/dev`. There is no requirement concerning major/minor number values.

`/dev/null`

An infinite data source and data sink. Data written to this device shall be discarded. Reads from this device shall always return end-of-file (EOF).

`/dev/zero`

This device is a source of zeroed out data. All data written to this device shall be discarded. A read from this device shall always return the requested number of bytes, each initialized to the value '\0'.

`/dev/tty`

In each process, a synonym for the controlling terminal associated with the process group of that process, if any. All reads and writes to this device shall behave as if the actual controlling terminal device had been opened.

16.2 `/etc`: Host-specific system configuration

In addition to the requirements for `/etc` in the Filesystem Hierarchy Standard, an LSB conforming system shall also provide the following directories or symbolic links to directories:

`/etc/cron.d`

A directory containing extended **crontab** files; see Cron Jobs.

`/etc/cron.daily`

A directory containing shell scripts to be executed once a day; see Cron Jobs.

`/etc/cron.hourly`

A directory containing shell scripts to be executed once per hour; see Cron Jobs.

`/etc/cron.monthly`

A directory containing shell scripts to be executed once per month; see Cron Jobs.

`/etc/cron.weekly`

A directory containing shell scripts to be executed once a week; see Cron Jobs.

`/etc/init.d`

A directory containing system initialization scripts; see Installation and Removal of Init Scripts.

`/etc/profile.d`

A directory containing shell scripts. Script names should follow the same conventions as specified for cron jobs (see Cron Jobs, but should have the suffix `.sh`. The behavior is unspecified if a script is installed in this directory that does not have the suffix `.sh`.

The **sh** utility shall read and execute commands in its current execution environment from all the shell scripts in this directory that have the suffix `.sh` when invoked as an interactive login shell, or if the `-l` (the letter *ell*) is specified (see Shell Invocation).

Future Directions: These directories are required at this version of the LSB since there is not yet an agreed method for abstracting the implementation so that applications need not be aware of these locations during installation. However, Future Directions describes a tool, **lsbinstall**, that will make these directories implementation specific and no longer required.

16.2.1 File Naming Conventions

~~Applications~~Conforming implemetnations and applications installing files into any of the above locations under `/etc` may only use filenames from the following managed namespaces:

- Assigned names. Such names must be chosen from the character set `[a-z0-9]`. In order to avoid conflicts these names shall be reserved through the Linux Assigned Names and Numbers Authority (LANANA). Information about the LANANA may be found at www.lanana.org (http://www.lanana.org).

  Note: Commonly used names should be reserved in advance; developers for projects are encouraged to reserve names from LANANA, so that each distribution can use the same name, and to avoid conflicts with other projects.

- Hierarchical names. Script names in this category take the form: `<hier1>-<hier2>-...-<name>`, where name is taken from the character set `[a-z0-9]`, and where there may be one or more `<hier-n>` components. `<hier1>` may either be an LSB provider name assigned by the LANANA, or it may be owners' DNS name in lower case, with at least one `'.'`. e.g. "`debian.org`",

"staroffice.sun.com", etc. The LSB provider name assigned by LANANA shall only consist of the ASCII characters [a-z0-9].

- Reserved names. Names that begin with the character '_' are reserved for distribution use only. These names should be used for essential system packages only.

  Note: A non-conforming application may still have polluted these managed namespaces with unregistered filenames; a conforming application should check for namespace collisions and take appropriate steps if they occur.

  In general, if a package or some system function is likely to be used on multiple systems, the package developers or the distribution should get a registered name through LANANA, and distributions should strive to use the same name whenever possible. For applications which may not be essential or may not be commonly installed, the hierarchical namespace may be more appropriate. An advantage to the hierarchical namespace is that there is no need to consult with the LANANA before obtaining an assigned name.

  Short names are highly desirable, since system administrators may need to manually start and stop services. Given this, they should be standardized on a per-package basis. This is the rationale behind having the LANANA organization assign these names. The LANANA may be called upon to handle other namespace issues, such as package/prerequisites naming.

16.3 User Accounting Databases

The Filesystem Hierarchy Standard specifies two optional locations for user accounting databases used by the getutent(), getutent_r(), getutxent(), getutxid(), getutxline(), and pututxline() functions. These are /var/run/utmp and /var/run/wtmp.

The LSB does not specify the format or structure of these files, or even if they are files at all. They should be used only as "magic cookies" to the utmpname() function.

16.4 Path For System Administration Utilities

Certain utilities used for system administration (and other privileged commands) may be stored in /sbin, /usr/sbin, and /usr/local/sbin. Applications requiring to use commands identified as system administration utilities should add these directories to their PATH. By default, as described in ISO POSIX (2003), standard utilities shall be found on the PATH returned by **getconf PATH** (or **command -p getconf PATH** to be guaranteed to invoke the correct version of **getconf**).

17 Additional Recommendations

17.1 Recommendations for applications on ownership and permissions

17.1.1 Directory Write Permissions

The application should not depend on having directory write permission in any directory except `/tmp`, `/var/tmp`, and the invoking user's home directory.

In addition, the application may store variable data in `/var/opt/`*`package`*, (where *`package`* is the name of the application package), if such a directory is created with appropriate permissions during the package installation.

For these directories the application should be able to work with directory write permissions restricted by the `S_ISVTXT` bit, implementing the restricted deletion mode as described for the XSI option for ISO POSIX (2003)..

17.1.2 File Write Permissions

The application should not depend on file write permission to any file that it does not itself create.

17.1.3 File Read and execute Permissions

The application should not depend on having read permission to every file and directory.

17.1.4 SUID and SGID Permissions

The application should not depend on the set user ID or set group ID (the `S_ISUID` or `S_ISGID` permission bits) permissions of a file not packaged with the application. Instead, the distribution is responsible for assuming that all system commands have the required permissions and work correctly.

> **Rationale:** In order to implement common security policies it is strongly advisable for applications to use the minimum set of security attributes necessary for correct operation. Applications that require substantial appropriate privilege are likely to cause problems with such security policies.

17.1.5 Privileged users

In general, applications should not depend on running as a privileged user. This specification uses the term "appropriate privilege" throughout to identify operations that cannot be achieved without some special granting of additional privilege.

Applications that have a reason to run with appropriate privilege should outline this reason clearly in their documentation. Users of the application should be informed, that "this application demands security privileges, which could interfere with system security".

The application should not contain binary-only software that requires being run with appropriate privilege, as this makes security auditing harder or even impossible.

17.1.6 Changing permissions

The application shall not change permissions of files and directories that do not belong to its own package. Should an application require that certain files and directories not directly belonging to the package have a particular ownership, the application shall document this requirement, and may fail during installation if the permissions on these files is inappropriate.

17.1.7 Removable Media (Cdrom, Floppy, etc.)

Applications that expect to be runnable from removable media should not depend on logging in as a privileged user, and should be prepared to deal with a restrictive environment. Examples of such restrictions could be default mount options that disable set-user/group-ID attributes, disabling block or character-special files on the medium, or remapping the user and group IDs of files away from any privileged value.

> **Rationale:** System vendors and local system administrators want to run applications from removable media, but want the possibility to control what the application can do.

17.1.8 Installable applications

Where the installation of an application needs additional privileges, it must clearly document all files and system databases that are modified outside of those in `/opt/`*`pkg-name`* and `/var/opt/`*`pkg-name`*, other than those that may be updated by system logging or auditing activities.

Without this, the local system administrator would have to blindly trust a piece of software, particularly with respect to its security.

18 Additional Behaviors

18.1 Mandatory Optional Behaviors

This section specifies behaviors in which there is optional behavior in one of the standards on which the LSB relies, and where the LSB requires a specific behavior.

> **Note:** The LSB does not require the kernel to be Linux; the set of mandated options reflects current existing practice, but may be modified in future releases.

LSB conforming implementations shall support the following options defined within the *ISO POSIX (2003)*:

_POSIX_FSYNC
_POSIX_MAPPED_FILES
_POSIX_MEMLOCK
_POSIX_MEMLOCK_RANGE
_POSIX_MEMORY_PROTECTION
_POSIX_PRIORITY_SCHEDULING
_POSIX_REALTIME_SIGNALS
_POSIX_THREAD_ATTR_STACKADDR
_POSIX_THREAD_ATTR_STACKSIZE
_POSIX_THREAD_PROCESS_SHARED
_POSIX_THREAD_SAFE_FUNCTIONS
_POSIX_THREADS

The `opendir()` function shall consume a file descriptor in the same fashion as `open()`, and therefore may fail with `EMFILE` or `ENFILE`.

The `START` and `STOP` `termios` characters shall be changeable, as described as optional behavior in the "General Terminal Interface" section of the *ISO POSIX (2003)*.

The `access()` function function shall fail with `errno` set to `EINVAL` if the *`amode`* argument contains bits other than those set by the bitwise inclusive OR of `R_OK`, `W_OK`, `X_OK` and `F_OK`.

The `link()` function shall require access to the existing file in order to succeed, as described as optional behavior in the *ISO POSIX (2003)*.

Calling `unlink()` on a directory shall fail. Calling `link()` specifying a directory as the first argument shall fail. See also unlink.

> **Note:** Linux allows `rename()` on a directory without having write access, but the LSB does not require this.

18.1.1 Special Requirements

LSB conforming systems shall enforce certain special additional restrictions above and beyond those required by ISO POSIX (2003).

> **Note:** These additional restrictions are required in order to support the testing and certification programs associated with the LSB. In each case, these are values that defined macros must not have; conforming applications that use these values shall trigger a failure in the interface that is otherwise described as a "may fail".

The `fcntl()` function shall treat the "cmd" value -1 as invalid.

The *whence* value `-1` shall be an invalid value for the `lseek()`, `fseek()` and `fcntl()` functions.

The value `-5` shall be an invalid signal number.

If the `sigaddset()` or `sigdelset()` functions are passed an invalid signal number, they shall return with EINVAL. Implementations are only required to enforce this requirement for signal numbers which are specified to be invalid by this specification (such as the `-5` mentioned above).

The mode value `-1` to the `access()` function shall be treated as invalid.

A value of `-1` shall be an invalid "_PC_..." value for `pathconf()`.

A value of `-1` shall be an invalid "_SC..." value for `sysconf()`.

The *nl_item* value `-1` shall be invalid for `nl_langinfo()`.

The value `-1` shall be an invalid "_CS_..." value for `confstr()`.

The value `"a"` shall be an invalid *mode* argument to `popen()`.

The `fcntl()` function shall fail and set `errno` to EDEADLK if the *cmd* argument is `F_SETLKW`, and the lock is blocked by a lock from another process already blocked by the current process.

The `opendir()` function shall consume a file descriptor; the `readdir()` function shall fail and set `errno` to EBADF if the underlying file descriptor is closed.

The `link()` function shall not work across file systems, and shall fail and set `errno` to EXDEV as described as optional behavior in ISO POSIX (2003).

19 Localization

19.1 Introduction

In order to install a message catalog, the installation procedure shall supply the message catalog in a format readable by the **msgfmt** utility, which shall be invoked to compile the message catalog into an appropriate binary format on the target system.

> **Rationale:** The original intent was to allow an application to contain the binary GNU MO format files. However, the format of these files is not officially stable, hence it is necessary to compile these catalogs on the target system. These binary catalogs may differ from architecture to architecture as well.

The resulting binary message catalog shall be located in the package's private area under `/opt`, and the application may use `bindtextdomain()` to specify this location.

Implementations shall support the POSIX and C locales as specified in ISO POSIX (2003). Other locales may be supported.

Implementations may define additional locale categories not defined by that standard.

> **Note:** Implementations choosing additional locale categories should be aware of ISO/IEC TR14652 and are advised not to choose names that conflict with that specification. If implementations provide locale categories whose names are part of the FDCC set of ISO/IEC TR14652, they should behave as defined by that specification.

19.2 Regular Expressions

Utilities that process regular expressions shall support Basic Regular Expressions and Extended Regular Expressions as specified in ISO POSIX (2003), with the following exceptions:

Range expression (such as `[a-z]`) can be based on code point order instead of collating element order.

Equivalence class expression (such as `[=a=]`) and multi-character collating element expression (such as `[.ch.]`) are optional.

Handling of a multi-character collating element is optional.

This affects at least the following utilities:

- **awk** (see awk)
- **grep** (see grep) (including **egrep**, see egrep)
- **sed** (see sed)

It also affects the behavior of interfaces in the base libraries, including at least

- `regexec()` (see regexec)

19.3 Pattern Matching Notation

Utilities that perform filename pattern matching (also known as Filename Globbing) shall do it as specified in ISO POSIX (2003), Pattern Matching Notation, with the following exceptions:

Pattern bracket expressions (such as `[a-z]`) can be based on code point order instead of collating element order.

Equivalence class expression (such as `[=a=]`) and multi-character collating element expression (such as `[.ch.]`) are optional.

Handling of a multi-character collating element is optional.

This affects at least the following utilities: **cpio** (cpio), **find** (find) and **tar** (tar).

VII System Initialization

20 System Initialization

20.1 Cron Jobs

In addition to the individual user `crontab` files specified by ISO POSIX (2003) stored under `/var/spool/cron`, the process that executes scheduled commands shall also process the following additional `crontab` files: `/etc/crontab`, `/etc/cron.d/*`. The installation of a package shall not modify the configuration file `/etc/crontab`.

If a package wishes to install a job that has to be executed periodically, it shall place an executable *cron script* in one of the following directories:

```
/etc/cron.hourly
/etc/cron.daily
/etc/cron.weekly
/etc/cron.monthly
```

As these directory names suggest, the files within them are executed on a hourly, daily, weekly, or monthly basis, respectively, under the control of an entry in one of the system `crontab` files, at an unspecified time of day. See below for the rules concerning the names of cron scripts.

> **Note:** It is recommended that cron scripts installed in any of these directories be script files rather than compiled binaries so that they may be modified by the local system administrator. Conforming applications may only install cron scripts which use an interpreter required by this specification or provided by this or another conforming application.
>
> This specification does not define the concept of a package *upgrade*. Implementations may do different things when packages are upgraded, including not replacing a cron script if it marked as a configuration file, particularly if the cron script appears to have been modified since installation. In some circumstances, the cron script may not be removed when the package is uninstalled. Applications should design their installation procedure and cron scripts to be robust in the face of such behavior. In particular, cron scripts should not fail obscurely if run in unexpected circumstances. Testing for the existence of application binaries before executing them is suggested.
>
> Future versions of this specification may remove the need to install file directly into these directories, and instead abstract the interface to the **cron** utility in such a way as to hide the implementation. Please see Future Directions.

If a certain task has to be executed at other than the predefined frequencies, the package shall install a file `/etc/cron.d/`*`cron-name`*. The file shall have the same format as that described for the **crontab** command in ISO POSIX (2003), except that there shall be an additional field, *`username`*, before the name of the command to execute. For completeness, the seven fields shall be:

1. Minute [0,59]
2. Hour [0,23]
3. Day of the month [1,31]
4. Month of the year [1,12]
5. Day of the week [0,6] (with 0=Sunday)
6. Username
7. command [args ...]

This file shall be processed by the system automatically, with the named command being run at the specified time, as the specified username.

Applications installing files in these directories shall use the LSB naming conventions (see File Naming Conventions).

20.2 Init Script Actions

Conforming applications which need to execute commands on changes to the system run level (including boot and shutdown), may install one or more *init scripts*. Init scripts provided by conforming applications shall accept a single argument which selects the action:

start	start the service
stop	stop the service
restart	stop and restart the service if the service is already running, otherwise start the service
try-restart	restart the service if the service is already running
reload	cause the configuration of the service to be reloaded without actually stopping and restarting the service
force-reload	cause the configuration to be reloaded if the service supports this, otherwise restart the service if it is running
status	print the current status of the service

The **start**, **stop**, **restart**, **force-reload**, and **status** actions shall be supported by all init scripts; the **reload** and the **try-restart** actions are optional. Other init-script actions may be defined by the init script.

Init scripts shall ensure that they will behave sensibly if invoked with **start** when the service is already running, or with **stop** when not running, and that they do not kill similarly-named user processes. The best way to achieve this is to use the init-script functions provided by `/lib/lsb/init-functions` (see Init Script Functions)

If a service reloads its configuration automatically (as in the case of cron, for example), the **reload** action of the init script shall behave as if the configuration was reloaded successfully. The **restart**, **try-restart**, **reload** and **force-reload** actions may be atomic; that is if a service is known not to be operational after a restart or reload, the script may return an error without any further action.

> **Note:** This specification does not define the concept of a package *upgrade*. Implementations may do different things when packages are upgraded, including not replacing an init script if it is marked as a configuration file, particularly if the file appears to have been modified since installation. In some circumstances, the init script may not be removed when the package is uninstalled. Applications should design their installation procedure and init scripts to be robust in the face of such behavior. In particular, init scripts should not fail obscurely if run in unexpected circumstances. Testing for the existence of application binaries before executing them is suggested.

If the **status** action is requested, the init script will return the following exit status codes.

0	program is running or service is OK
1	program is dead and /var/run pid file exists

2	program is dead and /var/lock lock file exists
3	program is not running
4	program or service status is unknown
5-99	reserved for future LSB use
100-149	reserved for distribution use
150-199	reserved for application use
200-254	reserved

For all other init-script actions, the init script shall return an exit status of zero if the action was successful. Otherwise, the exit status shall be non-zero, as defined below. In addition to straightforward success, the following situations are also to be considered successful:

- restarting a service (instead of reloading it) with the **force-reload** argument
- running **start** on a service already running
- running **stop** on a service already stopped or not running
- running **restart** on a service already stopped or not running
- running **try-restart** on a service already stopped or not running

In case of an error while processing any init-script action except for **status**, the init script shall print an error message and exit with a non-zero status code:

1	generic or unspecified error (current practice)
2	invalid or excess argument(s)
3	unimplemented feature (for example, "reload")
4	user had insufficient privilege
5	program is not installed
6	program is not configured
7	program is not running
8-99	reserved for future LSB use
100-149	reserved for distribution use
150-199	reserved for application use
200-254	reserved

Error and status messages should be printed with the logging functions (see Init Script Functions) `log_success_msg()`, `log_failure_msg()` and `log_warning_msg()`. Scripts may write to standard error or standard output, but implementations need not present text written to standard error/output to the user or do anything else with it.

> **Note:** Since init scripts may be run manually by a system administrator with non-standard environment variable values for PATH, USER, LOGNAME, etc., init scripts should not depend on the values of these environment variables. They should set them to some known/default values if they are needed.

20.3 Comment Conventions for Init Scripts

Conforming applications may install one or more init scripts. These init scripts must be activated by invoking the **install_initd** command. Prior to package removal, the changes applied by **install_initd** must be undone by invoking **remove_initd**. See Installation and Removal of Init Scripts for more details.

install_initd and **remove_initd** determine actions to take by decoding a specially formatted block of lines in the script. This block shall be delimited by the lines

```
### BEGIN INIT INFO
### END INIT INFO
```

The delimiter lines may contain trailing whitespace, which shall be ignored. All lines inside the block shall begin with a hash character `'#'` in the first column, so the shell interprets them as comment lines which do not affect operation of the script. The lines shall be of the form:

```
# {keyword}: arg1 [arg2...]
```

with exactly one space character between the `'#'` and the keyword, with a single exception. In lines following a line containing the **Description** keyword, and until the next keyword or block ending delimiter is seen, a line where the `'#'` is followed by more than one space or a tab character shall be treated as a continuation of the previous line.

The information extracted from the block is used by the installation tool or the init-script system to assure that init scripts are run in the correct order. It is unspecified whether the information is evaluated only when **install_initd** runs, when the init scripts are executed, or both. The information extracted includes run levels, defined in Run Levels, and boot facilities, defined in Facility Names.

The following keywords, with their arguments, are defined:

`Provides:` `boot_facility_1 [boot_facility_2...]`

boot facilities provided by this init script. When an init script is run with a **start** argument, the boot facility or facilities specified by the **Provides** keyword shall be deemed present and hence init scripts which require those boot facilities should be started later. When an init script is run with a **stop** argument, the boot facilities specified by the **Provides** keyword are deemed no longer present.

`Required-Start:` `boot_facility_1 [boot_facility_2...]`

facilities which must be available during startup of this service. The init-script system should insure init scripts which provide the **Required-Start** facilities are started before starting this script.

`Required-Stop:` `boot_facility_1 [boot_facility_2...]`

facilities which must be available during the shutdown of this service. The init-script system should avoid stopping init scripts which provide the **Required-Stop** facilities until this script is stopped.

`Should-Start:` `boot_facility_1 [boot_facility_2...]`

facilities which, if present, should be available during startup of this service. This allows for weak dependencies which do not cause the service to fail if a facility is not available. The service may provide reduced functionality in this situation. Conforming applications should not rely on the existence of this feature.

`Should-Stop:` `boot_facility_1 [boot_facility_2...]`

facilities which should be available during shutdown of this service.

Default-Start: run_level_1 [run_level_2...]
Default-Stop: run_level_1 [run_level_2...]

which run levels should by default run the init script with a **start** (**stop**) argument to start (stop) the services controlled by the init script.

For example, if a service should run in runlevels 3, 4, and 5 only, specify "Default-Start: 3 4 5" and "Default-Stop: 0 1 2 6".

Short-Description: short_description

provide a brief description of the actions of the init script. Limited to a single line of text.

Description: multiline_description

provide a more complete description of the actions of the init script. May span mulitple lines. In a multiline description, each continuation line shall begin with a '#' followed by tab character or a '#' followed by at least two space characters. The multiline description is terminated by the first line that does not match this criteria.

Additional keywords may be defined in future versions of this specification. Also, implementations may define local extensions by using the prefix ***X-implementor***. For example, **X-RedHat-foobardecl**, or **X-Debian-xyzzydecl**.

Example:

```
### BEGIN INIT INFO
     # Provides: lsb-ourdb
     # Required-Start: $local_fs $network $remote_fs
     # Required-Stop: $local_fs $network $remote_fs
     # Default-Start:  2 3 4 5
     # Default-Stop: 0 1 6
     # Short-Description: start and stop OurDB
     # Description: OurDB is a very fast and reliable database
     #        engine used for illustrating init scripts
     ### END INIT INFO
```

The comment conventions described in this section are only required for init scripts installed by conforming applications. Conforming runtime implementations are not required to use this scheme in their system provided init scripts.

Note: This specification does not require, but is designed to allow, the development of a system which runs init scripts in parallel. Hence, enforced-serialization of scripts is avoided unless it is explicitly necessary.

20.4 Installation and Removal of Init Scripts

Conforming applications may install one or more initialization scripts (or *init scripts*). An init script shall be installed in `/etc/init.d` (which may be a symbolic link to another location), by the package installer.

Note: The requirement to install scripts in `/etc/init.d` may be removed in future versions of this specification. See Host-specific system configuration and Future Directions for further details.

During the installer's post-install processing phase the program **/usr/lib/lsb/install_initd** must be called to activate the init script. Activation consists of arranging for the init script to be called in the correct order on system run-level

changes (including system boot and shutdown), based on dependencies supplied in the init script (see Comment Conventions for Init Scripts). The **install_initd** command should be thought of as a wrapper which hides the implementation details; how any given implementation arranges for the init script to be called at the appropriate time is not specified.

Example: if an init script specified "Default-Start: 3 4 5" and "Default-Stop: 0 1 2 6", **install_initd** might create "start" symbolic links with names starting with 'S' in `/etc/rc3.d`, `/etc/rc4.d` and `/etc/rc5.d` and "stop" symbolic links with names starting with 'K' in `/etc/rc0.d`, `/etc/rc1.d`, `/etc/rc2.d` and `/etc/rc6.d`. Such a scheme would be similar to the System V Init mechanism, but is by no means the only way this specification could be implemented.

The **install_initd** command takes a single argument, the full pathname of the installed init script. The init script must already be installed in `/etc/init.d`. The **install_initd** command will not copy it there, only activate it once it has been installed. For example:

```
/usr/lib/lsb/install_initd /etc/init.d/example.com-coffeed
```

The **install_initd** command shall return an exit status of zero if the init-script activation was successful or if the init script was already activated. If the dependencies in the init script (see Comment Conventions for Init Scripts) cannot be met, an exit status of one shall be returned and the init script shall not be activated.

When a software package is removed, **/usr/lib/lsb/remove_initd** must be called to deactivate the init script. This must occur before the init script itself is removed, as the dependency information in the script may be required for successful completion. Thus the installer's pre-remove processing phase must call **remove_initd**, and pass the full pathname of the installed init script. The package installer is still responsible for removing the init script. For example:

```
/usr/lib/lsb/remove_initd /etc/init.d/example.com-coffeed
```

The **remove_initd** program shall return an exit status of zero if the init script has been successfully deactivated or if the init script is not activated. If another init script which depends on a boot facility provided by this init script is activated, an exit status of one shall be returned and the init script shall remain activated. The installer must fail on such an exit code so it does not subsequently remove the init script.

Note: This specification does not describe a mechanism for the system administrator to manipulate the run levels at which an init script is started or stopped. There is no assurance that modifying the comment block for this purpose will have the desired effect.

20.5 Run Levels

The following *run levels* are specified for use by the **Default-Start** and **Default-Stop** actions defined in Comment Conventions for Init Scripts as hints to the **install_initd** command. Conforming implementations are not required to provide these exact run levels or give them the meanings described here, and may map any level described here to a different level which provides the equivalent functionality. Applications may not depend on specific run-level numbers.

0	halt
1	single user mode
2	multiuser with no network services

	exported
3	normal/full multiuser
4	reserved for local use, default is normal/full multiuser
5	multiuser with a display manager or equivalent
6	reboot

Note: These run levels were chosen as reflecting the most frequent existing practice, and in the absence of other considerations, implementors are strongly encouraged to follow this convention to provide consistency for system administrators who need to work with multiple distributions.

20.6 Facility Names

Boot *facilities* are used to indicate dependencies in initialization scripts, as defined in Comment Conventions for Init Scripts. Facility names are assigned to scripts by the **Provides:** keyword. Facility names that begin with a dollar sign (`'$'`) are reserved system facility names.

Note: Facility names are only recognized in the context of the init script comment block and are not available in the body of the init script. In particular, the use of the leading '$' character does not imply system facility names are subject to shell variable expansion, since they appear inside comments.

Conforming applications shall not provide facilities that begin with a dollar sign. Implementations shall provide the following facility names:

$local_fs

all local file systems are mounted

$network

basic networking support is available. Example: a server program could listen on a socket.

$named

IP name-to-address translation, using the interfaces described in this specification, are available to the level the system normally provides them. Example: if a DNS query daemon normally provides this facility, then that daemon has been started.

$portmap

daemons providing SunRPC/ONCRPC portmapping service as defined in RFC 1833: Binding Protocols for ONC RPC Version 2 (if present) are running.

$remote_fs

all remote file systems are available. In some configurations, file systems such as `/usr` may be remote. Many applications that require **$local_fs** will probably also require **$remote_fs**.

$syslog

system logger is operational.

$time

the system time has been set, for example by using a network-based time program such as **ntp** or **rdate**, or via the hardware Real Time Clock.

Other (non-system) facilities may be defined by other conforming applications. These facilities shall be named using the same conventions defined for naming init scripts (see Script Names). Commonly, the facility provided by a conforming init script will have the same name as the name assigned to the init script.

20.7 Script Names

Since init scripts live in a single directory, they must share a single namespace. To avoid conflicts, applications installing files in this directories shall use the LSB naming conventions (see File Naming Conventions).

20.8 Init Script Functions

Each conforming init script shall execute the commands in the file `/lib/lsb/init-functions` in the current environment (see shell special built-in command **dot**). This file shall cause the following shell script commands to be defined in an unspecified manner.

Note: This can be done either by adding a directory to the PATH variable which defines these commands, or by defining shell aliases or functions.

Although the commands made available via this mechanism need not be conforming applications in their own right, applications that use them should only depend on features described in this specification.

Conforming scripts shall not specify the "exit on error" option (i.e. **set -e**) when sourcing this file, or calling any of the commands thus made available.

The **start_daemon**, **killproc** and **pidofproc** functions shall use the following algorithm for determining the status and the process identifiers of the specified program.

1. If the `-p` *`pidfile`* option is specified, and the named `pidfile` exists, a single line at the start of the `pidfile` shall be read. If this line contains one or more numeric values, separated by spaces, these values shall be used. If the `-p` *`pidfile`* option is specified and the named `pidfile` does not exist, the functions shall assume that the daemon is not running.
2. Otherwise, `/var/run/`*`basename`*`.pid` shall be read in a similar fashion. If this contains one or more numeric values on the first line, these values shall be used. Optionally, implementations may use unspecified additional methods to locate the process identifiers required.

The method used to determine the status is implementation defined, but should allow for non-binary programs.

Note: Commonly used methods check either for the existence of the `/proc/pid` directory or use `/proc/pid/exe` and `/proc/pid/cmdline`. Relying only on `/proc/pid/exe` is discouraged since this specification does not specify the existence of, or semantics for, `/proc`. Additionally, using `/proc/pid/exe` may result in a not-running status for daemons that are written in a script language.

Conforming implementations may use other mechanisms besides those based on pidfiles, unless the `-p` *`pidfile`* option has been used. Conforming applications should not rely on such mechanisms and should always use a `pidfile`. When a

program is stopped, it should delete its `pidfile`. Multiple process identifiers shall be separated by a single space in the `pidfile` and in the output of **pidofproc**.

`start_daemon` `[-f] [-n nicelevel] [-p pidfile] pathname [args...]`

runs the specified program as a daemon. The **start_daemon** function shall check if the program is already running using the algorithm given above. If so, it shall not start another copy of the daemon unless the *`-f`* option is given. The *`-n`* option specifies a nice level. See **nice**. **start_daemon** shall return the LSB defined exit status codes. It shall return 0 if the program has been successfully started or is running and not 0 otherwise.

`killproc` `[-p pidfile] pathname [signal]`

The **killproc** function shall stop the specified program. The program is found using the algorithm given above. If a signal is specified, using the *`-signal_name`* or *`-signal_number`* syntaxes as specified by the **kill** command, the program is sent that signal. Otherwise, a `SIGTERM` followed by a `SIGKILL` after an unspecified number of seconds shall be sent. If a program has been terminated, the `pidfile` should be removed if the terminated process has not already done so. The **killproc** function shall return the LSB defined exit status codes. If called without a signal, it shall return 0 if the program has been stopped or is not running and not 0 otherwise. If a signal is given, it shall return 0 only if the program is running.

`pidofproc` `[-p pidfile] pathname`

The **pidofproc** function shall return one or more process identifiers for a particular daemon using the algorithm given above. Only process identifiers of running processes should be returned. Multiple process identifiers shall be separated by a single space.

Note: A process may exit between **pidofproc** discovering its identity and the caller of **pidofproc** being able to act on that identity. As a result, no test assertion can be made that the process identifiers returned by **pidofproc** *shall* be running processes.

The **pidofproc** function shall return the LSB defined exit status codes for "status". It shall return 0 if the program is running and not 0 otherwise.

`log_success_msg` `message`

The **log_success_msg** function shall cause the system to ~~print~~write a success message to an unspecified log file. The format of the message is unspecified. The **log_success_msg** function may also write a message to the standard output.

Note: The message should be relatively short; no more than 60 characters is highly desirable.

`log_failure_msg` `message`

The **log_failure_msg** function shall cause the system to ~~print~~write a failure message to an unspecified log file. The format of the message is unspecified. The **log_failure_msg** function may also write a message to the standard output.

Note: The message should be relatively short; no more than 60 characters is highly desirable.

345 **`log_warning_msg`** `message`

346 The **log_warning_msg** function shall cause the system to ~~print~~write a warning
347 message to an unspecified log file. The format of the message is unspecified.
348 The **log_warning_msg** function may also write a message to the standard
349 output.

350 **Note:** The message should be relatively short; no more than 60 characters is highly
351 desirable.

VIII Users & Groups

21 Users & Groups

21.1 User and Group Database

The format of the User and Group databases is not specified. Programs may only read these databases using the provided API. Changes to these databases should be made using the provided commands.

21.2 User & Group Names

Table 21-1 describes required mnemonic user and group names. This specification makes no attempt to numerically assign user or group identity numbers, with the exception that both the User ID and Group ID for the user `root` shall be equal to 0.

Table 21-1 Required User & Group Names

User	Group	Comments
root	root	Administrative user with all appropriate privileges
bin	bin	Legacy User ID/Group ID[a]
daemon	daemon	Legacy User ID/Group ID[b]

Notes:
a The `bin` User ID/Group ID is included for compatibility with legacy applications. New applications should no longer use the `bin` User ID/Group ID.
b The `daemon` User ID/Group ID was used as an unprivileged User ID/Group ID for daemons to execute under in order to limit their access to the system. Generally daemons should now run under individual User ID/Group IDs in order to further partition daemons from one another.

Table 21-2 is a table of optional mnemonic user and group names. This specification makes no attempt to numerically assign uid or gid numbers. If the username exists on a system, then they should be in the suggested corresponding group. These user and group names are for use by distributions, not by applications.

Table 21-2 Optional User & Group Names

User	Group	Comments
adm	adm	Administrative special privileges
lp	lp	Printer special privileges
sync	sync	Login to sync the system
shutdown	shutdown	Login to shutdown the system
halt	halt	Login to halt the system

User	Group	Comments
mail	mail	Mail special privileges
news	news	News special privileges
uucp	uucp	UUCP special privileges
operator	root	Operator special privileges
man	man	Man special privileges
nobody	nobody	Used by NFS

Only a minimum working set of "user names" and their corresponding "user groups" are required. Applications cannot assume non system user or group names will be defined.

Applications cannot assume any policy for the default file creation mask (**umask**) or the default directory permissions a user may have. Applications should enforce user only file permissions on private files such as mailboxes. The location of the users home directory is also not defined by policy other than the recommendations of the Filesystem Hierarchy Standard and should be obtained by the `getpwnam()`, `getpwnam_r()`, `getpwent()`, `getpwuid()`, and `getpwuid_r()` functions.

21.3 User ID Ranges

The system User IDs from 0 to 99 should be statically allocated by the system, and shall not be created by applications.

The system User IDs from 100 to 499 should be reserved for dynamic allocation by system administrators and post install scripts using **useradd**.

21.4 Rationale

The purpose of specifying optional users and groups is to reduce the potential for name conflicts between applications and distributions.

IX Package Format and Installation

22 Software Installation

22.1 Introduction

Applications shall either be packaged in the RPM packaging format as defined in this specification, or supply an installer which is LSB conforming (for example, calls LSB commands and utilities).

> **Note:** Supplying an RPM format package is encouraged because it makes systems easier to manage. ~~A future version of the LSB may~~This specification does not require the implementation to use RPM~~, or specify a way for an installer to update a~~ as the package ~~database~~manager; it only specifies the format of the package file.
>
> Applications are also encouraged to uninstall cleanly.

~~Distributions~~A package in RPM format may include a dependency on the LSB Core and other LSB specifications, as described in Section 22.6. Packages that are not in RPM format may test for the presence of a conforming implementation by means of the **lsb_release** utility.

Implementations shall provide a mechanism for installing applications in this packaging format with some restrictions listed below.

> **Note:** The ~~distribution~~implementation itself may use a different packaging format for its own packages, and of course it may use any available mechanism for installing the LSB-conformant packages.

22.2 Package File Format

An RPM format file consists of 4 sections, the Lead, Signature, Header, and the Payload. All values are stored in network byte order.

Table 22-1 RPM File Format

Lead
Signature
Header
Payload

These 4 sections shall exist in the order specified.

The lead section is used to identify the package file.

The signature section is used to verify the integrity, and optionally, the authenticity of the majority of the package file.

The header section contains all available information about the package. Entries such as the package's name, version, and file list, are contained in the header.

The payload section holds the files to be installed.

22.2.1 Lead Section

```
struct rpmlead {
    unsigned char magic[4];
    unsigned char major, minor;
    short type;
```

```
    short archnum;
    char name[66];
    short osnum;
    short signature_type;
    char reserved[16];
} ;
```

magic

Value identifying this file as an RPM format file. This value shall be "\355\253\356\333".

major

Value indicating the major version number of the file format version. This value shall be 3.

minor

Value indicating the minor revision number of file format version. This value shall be 0.

type

Value indicating whether this is a source or binary package. This value shall be 0 to indicate a binary package.

archnum

Value indicating the architecture for which this package is valid. This value is specified in the architecture- specific ~~LSB specification~~supplement.

name

A NUL terminated string that provides the package name. This name shall conform with the Package Naming section of this specification.

osnum

Value indicating the Operating System for which this package is valid. This value shall be 1.

signature_type

Value indicating the type of the signature used in the Signature part of the file. This value shall be 5.

reserved

Reserved space. The value is undefined.

22.2.2 Header Structure

The Header structure is used for both the Signature and Header Sections. A Header Structure consists of 3 parts, a Header record, followed by 1 or more Index records, followed by 0 or more bytes of data associated with the Index records. A Header structure shall be aligned to an 8 byte boundary.

Table 22-2 Signature Format

Header Record
Array of Index Records

Store of Index Values

22.2.2.1 Header Record

```
struct rpmheader {
    unsigned char magic[4];
    unsigned char reserved[4];
    int nindex;
    int hsize;
    } ;
```

magic

Value identifying this record as an RPM header record. This value shall be `"\216\255\350\001"`.

reserved

Reserved space. This value shall be `"\000\000\000\000"`.

nindex

The number of Index Records that follow this Header Record. There should be at least 1 Index Record.

hsize

The size in bytes of the storage area for the data pointed to by the Index Records.

22.2.2.2 Index Record

```
struct rpmhdrindex {
    int tag;
    int type;
    int offset;
    int count;
    } ;
```

tag

Value identifying the purpose of the data associated with this Index Record. The value of this field is dependent on the context in which the Index Record is used, and is defined below and in later sections.

type

Value identifying the type of the data associated with this Index Record. The possible *type* values are defined below.

offset

Location in the Store of the data associated with this Index Record. This value should between 0 and the value contained in the *hsize* of the Header Structure.

count

Size of the data associated with this Index Record. The *count* is the number of elements whose size is defined by the type of this Record.

22.2.2.2.1 Index Type Values

The possible values for the *type* field are defined in this table.

111 **Table 22-3 Index Type values**

Type	Value	Size (in bytes)	Alignment
RPM_NULL_TYPE	0	Not Implemented.	
RPM_CHAR_TYPE	1	1	1
RPM_INT8_TYPE	2	1	1
RPM_INT16_TYPE	3	2	2
RPM_INT32_TYPE	4	4	4
RPM_INT64_TYPE	5	Reserved.	
RPM_STRING_TYPE	6	variable, NUL terminated	1
RPM_BIN_TYPE	7	1	1
RPM_STRING_ARRAY_TYPE	8	Variable, sequence of NUL terminated strings	1
RPM_I18NSTRING_TYPE	9	variable, sequence of NUL terminated strings	1

112

113 The string arrays specified for entries of type RPM_STRING_ARRAY_TYPE and
114 RPM_I18NSTRING_TYPE are vectors of strings in a contiguous block of memory, each
115 element separated from its neighbors by a NUL character.

116 Index records with type RPM_I18NSTRING_TYPE shall always have a *count* of 1. The
117 array entries in an index of type RPM_I18NSTRING_TYPE correspond to the locale
118 names contained in the RPMTAG_HDRI18NTABLE index.

119 *22.2.2.2.2 Index Tag Values*

120 Some values are designated as header private, and may appear in any header
121 structure. These are defined here. Additional values are defined in later sections.

122 **Table 22-4 Header Private Tag Values**

Name	Tag Value	Type	Count	Status
RPMTAG_HEADERSIGNATURES	62	BIN	16	Optional
RPMTAG_HEADERIMMUTABLE	63	BIN	16	Optional
RPMTAG_HEADERI18NTABLE	100	STRING_ARRAY		~~Required~~Optional

123

124 RPMTAG_HEADERSIGNATURES

125 The signature tag differentiates a signature header from a metadata header, and
126 identifies the original contents of the signature header.

RPMTAG_HEADERIMMUTABLE

This tag contains an index record which specifies the portion of the Header Record which was used for the calculation of a signature. This data shall be preserved or any header-only signature will be invalidated.

RPMTAG_HEADERI18NTABLE

Contains a list of locales for which strings are provided in other parts of the package.

Not all Index records defined here will be present in all packages. Each tag value has a status which is defined here.

Required

This Index Record shall be present.

Optional

This Index Record may be present.

Informational

This Index Record may be present, but does not contribute to the processing of the package.

Deprecated

This Index Record should not be present.

Obsolete

This Index Record shall not be present.

Reserved

This Index Record shall not be present.

22.2.2.3 Header Store

The header store contains the values specified by the Index structures. These values are aligned according to their type and padding is used if needed. The store is located immediately following the Index structures.

22.2.3 Signature Section

The Signature section is implemented using the Header structure. The signature section defines the following additional tag values which may be used in the Index structures.

These values exist to provide additional information about the rest of the package.

Table 22-5 Signature Tag Values

Name	Tag Value	Type	Count	Status
~~SIGTAG_SIGSIZE~~RPMSIGTAG_SIZE	1000	INT32	1	Required
RPMSIGTAG_PAYLOADSIZE	1007	INT32	1	Optional

~~SIGTAG_SIG~~RPMSIGTAG_SIZE

This tag specifies the combined size of the Header and Payload sections.

RPMSIGTAG_PAYLOADSIZE

This tag specifies the uncompressed size of the Payload archive, including the cpio headers.

These values exist to ensure the integrity of the rest of the package.

Table 22-6 Signature Digest Tag Values

Name	Tag Value	Type	Count	Status
~~SIGTAG_MD5~~RPMSIGTAG_SHA1	~~1004~~269	~~BIN~~STRING	1~~6~~	~~Required~~Optional
~~SIGTAG_SHA1HEADER~~RPMSIGTAG_MD5	~~1010~~1004	~~STRING~~BIN	16	~~Optional~~Required

~~SIGTAG_MD5~~

~~This tag specifies the 128-bit MD5 checksum of the combined Header and Archive sections.~~

~~SIGTAG_SHA1HEADER~~

RPMSIGTAG_SHA1

This index contains the SHA1 checksum of the entire Header Section, including the Header Record, Index Records and Header store.

RPMSIGTAG_MD5

This tag specifies the 128-bit MD5 checksum of the combined Header and Archive sections.

These values exist to provide authentication of the package.

Table 22-7 Signature Signing Tag Values

Name	Tag Value	Type	Count	Status
~~SIGTAG_PGP~~RPMSIGTAG_DSA	~~1002~~267	BIN	1	Optional
~~SIGTAG_GPG~~RPMSIGTAG_RSA	~~1005~~268	BIN	~~65~~1	Optional
~~SIGTAG_DSAHEADER~~RPMSIGTAG_PGP	~~1011~~1002	BIN	1	Optional
~~SIGTAG_RSAHEADER~~RPMSIGTAG_GPG	~~1012~~1005	BIN	~~1~~65	Optional

~~SIGTAG_PGP~~RPMSIGTAG_DSA

~~This~~ The tag ~~specifies~~contains the ~~RSA~~DSA signature of the ~~combined~~ Header ~~and Payload sections~~section. The data is formatted as a Version 3 Signature Packet as specified in RFC 2440: OpenPGP Message Format.

If this tag is present,then the SIGTAG_GPG tag shall also be present.

RPMSIGTAG_RSA

The tag contains the ~~DSA~~RSA signature of the ~~combined~~ Header ~~and Payload sections.~~ section.The data is formatted as a Version 3 Signature Packet as specified in RFC 2440: OpenPGP Message Format.

~~SIGTAG_DSAHEADER~~

~~The~~ If this tag ~~contains~~is present, then the ~~DSA~~SIGTAG_PGP shall also be present.

RPMSIGTAG_PGP

This tag specifies the RSA signature of the combined Header ~~section~~and Payload sections. The data is formatted as a Version 3 Signature Packet as specified in RFC 2440: OpenPGP Message Format. ~~If this tag is present,then the~~

RPMSIGTAG_GPG ~~tag shall also be present.~~

~~SIGTAG_RSAHEADER~~

The tag contains the ~~RSA~~DSA signature of the combined Header ~~section.~~and Payload sections. The data is formatted as a Version 3 Signature Packet as specified in RFC 2440: OpenPGP Message Format~~. If this tag is present, then the SIGTAG_PGP shall also be present~~.

22.2.4 Header Section

The Header section is implemented using the Header structure. The Header section defines the following additional tag values which may be used in the Index structures.

22.2.4.1 Package Information

The following tag values are used to indicate information that describes the package as a whole.

Table 22-8 Package Info Tag Values

Name	Tag Value	Type	Count	Status
RPMTAG_NAME	1000	STRING	1	Required
RPMTAG_VERSION	1001	STRING	1	Required
RPMTAG_RELEASE	1002	STRING	1	Required
RPMTAG_SUMMARY	1004	I18NSTRING	1	Required
RPMTAG_DESCRIPTION	1005	I18NSTRING	1	Required

Name	Tag Value	Type	Count	Status
RPMTAG_SIZE	1009	INT32	1	Required
RPMTAG_DISTRIBUTION	1010	STRING	1	Informational
RPMTAG_VENDOR	1011	STRING	1	Informational
RPMTAG_LICENSE	1014	STRING	1	Required
RPMTAG_PACKAGER	1015	STRING	1	Informational
RPMTAG_GROUP	1016	I18NSTRING	1	Required
RPMTAG_URL	1020	STRING	1	Informational
RPMTAG_OS	1021	STRING	1	Required
RPMTAG_ARCH	1022	STRING	1	Required
RPMTAG_SOURCERPM	1044	STRING	1	Informational
RPMTAG_ARCHIVESIZE	1046	INT32	1	Optional
RPMTAG_RPMVERSION	1064	STRING	1	Informational
RPMTAG_COOKIE	1094	STRING	1	Optional
RPMTAG_DISTURL	1123	STRING	1	Informational
RPMTAG_PAYLOADFORMAT	1124	STRING	1	Required
RPMTAG_PAYLOADCOMPRESSOR	1125	STRING	1	Required
RPMTAG_PAYLOADFLAGS	1126	STRING	1	Required

RPMTAG_NAME

This tag specifies the name of the package.

RPMTAG_VERSION

This tag specifies the version of the package.

RPMTAG_RELEASE

This tag specifies the release of the package.

RPMTAG_SUMMARY

This tag specifies the summary description of the package. The summary value pointed to by this index record contains a one line description of the package.

RPMTAG_DESCRIPTION

This tag specifies the description of the package. The description value pointed to by this index record contains a full desription of the package.

RPMTAG_SIZE

This tag specifies the sum of the sizes of the regular files in the archive.

RPMTAG_DISTRIBUTION

A string containing the name of the distribution on which the package was built.

RPMTAG_VENDOR

A string containing the name of the organization that produced the package.

RPMTAG_LICENSE

This tag specifies the license which applies to this package.

RPMTAG_PACKAGER

A string identifying the tool used to build the package.

RPMTAG_GROUP

This tag specifies the administrative group to which this package belongs.

RPMTAG_URL

Generic package information URL

RPMTAG_OS

This tag specifies the OS of the package. The OS value pointed to by this index record shall be "linux".

RPMTAG_ARCH

This tag specifies the architecture of the package. The architecture value pointed to by this index record is defined in architecture specific LSB specification.

RPMTAG_SOURCERPM

This tag specifies the name of the source RPM

RPMTAG_ARCHIVESIZE

This tag specifies the uncompressed size of the Payload archive, including the cpio headers.

RPMTAG_RPMVERSION

This tag indicates the version of RPM tool used to build this package. The value is unused.

RPMTAG_COOKIE

This tag contains an opaque string whose contents are undefined.

RPMTAG_DISTURL

URL for package

RPMTAG_PAYLOADFORMAT

This tag specifies the format of the Archive section. The format value pointed to by this index record shall be 'cpio'.

RPMTAG_PAYLOADCOMPRESSOR

This tag specifies the compression used on the Archive section. The compression value pointed to by this index record shall be 'gzip'

RPMTAG_PAYLOADFLAGS

This tag indicates the compression level used for the Payload. This value shall always be '9'.

22.2.4.2 Installation Information

The following tag values are used to provide information needed during the installation of the package.

Table 22-9 Installation Tag Values

Name	Tag Value	Type	Count	Status
RPMTAG_PREIN	1023	STRING	1	Optional
RPMTAG_POSTIN	1024	STRING	1	Optional
RPMTAG_PREUN	1025	STRING	1	Optional
RPMTAG_POSTUN	1026	STRING	1	Optional
RPMTAG_PREINPROG	1085	STRING	1	Optional
RPMTAG_POSTINPROG	1086	STRING	1	Optional
RPMTAG_PREUNPROG	1087	STRING	1	Optional
RPMTAG_POSTUNPROG	1088	STRING	1	Optional

RPMTAG_PREIN

This tag specifies the preinstall scriptlet. If present, then RPMTAG_PREINPROG shall also be present.

RPMTAG_POSTIN

This tag specifies the postinstall scriptlet. If present, then RPMTAG_POSTINPROG shall also be present.

RPMTAG_PREUN

his tag specifies the preuninstall scriptlet. If present, then RPMTAG_PREUNPROG shall also be present.

RPMTAG_POSTUN

This tag specified the postuninstall scriptlet. If present, then RPMTAG_POSTUNPROG shall also be present.

RPMTAG_PREINPROG

This tag specifies the name of the intepreter to which the preinstall scriptlet will be passed. The intepreter pointed to by this index record shall be `/bin/sh`.

RPMTAG_POSTINPROG

This tag specifies the name of the intepreter to which the postinstall scriptlet will be passed. The intepreter pointed to by this index record shall be `/bin/sh`.

RPMTAG_PREUNPROG

This tag specifies the name of the intepreter to which the preuninstall scriptlet will be passed. The intepreter pointed to by this index record shall be `/bin/sh`.

RPMTAG_POSTUNPROG

This program specifies the name of the intepreter to which the postuninstall scriptlet will be passed. The intepreter pointed to by this index record shall be `/bin/sh`.

22.2.4.3 File Information

The following tag values are used to provide information about the files in the payload. This information is provided in the header to allow more efficient access of the information.

Table 22-10 File Info Tag Values

Name	Tag Value	Type	Count	Status
RPMTAG_OLDFILENAMES	1027	STRING_ARRAY		Optional
RPMTAG_FILESIZES	1028	INT32		Required
RPMTAG_FILEMODES	1030	INT16		Required
RPMTAG_FILERDEVS	1033	INT16		Required
RPMTAG_FILEMTIMES	1034	INT32		Required
RPMTAG_FILEMD5S	1035	STRING_ARRAY		Required
RPMTAG_FILELINKTOS	1036	STRING_ARRAY		Required
RPMTAG_FILEFLAGS	1037	INT32		Required
RPMTAG_FILEUSERNAME	1039	STRING_ARRAY		Required

Name	Tag Value	Type	Count	Status
RPMTAG_FILEGROUPNAME	1040	STRING_ARRAY		Required
RPMTAG_FILEDEVICES	1095	INT32		Required
RPMTAG_FILEINODES	1096	INT32		Required
RPMTAG_FILELANGS	1097	STRING_ARRAY		Required
RPMTAG_DIRINDEXES	1116	INT32		Optional
RPMTAG_BASENAMES	1117	STRING_ARRAY		Optional
RPMTAG_DIRNAMES	1118	STRING_ARRAY		Optional

RPMTAG_OLDFILENAMES

This tag specifies the filenames when not in a compressed format as determined by the absence of rpmlib(CompressedFileNames) in the RPMTAG_REQUIRENAME index.

RPMTAG_FILESIZES

This tag specifies the size of each file in the archive.

RPMTAG_FILEMODES

This tag specifies the mode of each file in the archive.

RPMTAG_FILERDEVS

This tag specifies the device number from which the file was copied.

RPMTAG_FILEMTIMES

This tag specifies the modification time in seconds since the epoch of each file in the archive.

RPMTAG_FILEMD5S

This tag specifies the ASCII representation of the MD5 sum of the corresponding file contents. This value is empty if the corresponding archive entry is not a regular file.

RPMTAG_FILELINKTOS

The target for a symlink, otherwise NULL.

RPMTAG_FILEFLAGS

This tag specifies the bit(s) to classify and control how files are to be installed. See below.

RPMTAG_FILEUSERNAME

This tag specifies the owner of the corresponding file.

RPMTAG_FILEGROUPNAME

This tag specifies the group of the corresponding file.

RPMTAG_FILEDEVICES

This tag specifies the 16 bit device number from which the file was copied.

RPMTAG_FILEINODES

This tag specifies the inode value from the original file system on the the system on which it was built.

RPMTAG_FILELANGS

This tag specifies a per-file locale marker used to install only locale specific subsets of files when the package is installed.

RPMTAG_DIRINDEXES

This tag specifies the index into the array provided by the RPMTAG_DIRNAMES Index which contains the directory name for the corresponding filename.

RPMTAG_BASENAMES

This tag specifies the base portion of the corresponding filename.

RPMTAG_DIRNAMES

One of RPMTAG_OLDFILENAMES or the tuple RPMTAG_DIRINDEXES, RPMTAG_BASENAMES, RPMTAG_DIRNAMES shall be present, but not both.

22.2.4.3.1 File Flags

The RPMTAG_FILEFLAGS tag value shall identify various characteristics of the file in the payload that it describes. It shall be an INT32 value consisting of either the value RPMFILE_NONE (0) or the bitwise inclusive or of one or more of the following values:

Table 22-11 File Flags

Name	Value
RPMFILE_CONFIG	(1 << 0)
RPMFILE_DOC	(1 << 1)
RPMFILE_DONOTUSE	(1 << 2)
RPMFILE_MISSINGOK	(1 << 3)
RPMFILE_NOREPLACE	(1 << 4)
RPMFILE_SPECFILE	(1 << 5)
RPMFILE_GHOST	(1 << 6)
RPMFILE_LICENSE	(1 << 7)
RPMFILE_README	(1 << 8)
RPMFILE_EXCLUDE	(1 << 9)

These bits have the following meaning:

`RPMFILE_CONFIG`

The file is a configuration file, and an existing file should be saved during a package upgrade operation and not removed during a pakage removal operation.

`RPMFILE_DOC`

The file contains documentation.

`RPMFILE_DONOTUSE`

This value is reserved for future use; conforming packages may not use this flag.

`RPMFILE_MISSINGOK`

The file need not exist on the installed system.

`RPMFILE_NOREPLACE`

Similar to the `RPMFILE_CONFIG`, this flag indicates that during an upgrade operation the original file on the system should not be altered.

`RPMFILE_SPECFILE`

The file is a package specification.

`RPMFILE_GHOST`

The file is not actually included in the payload, but should still be considered as a part of the package. For example, a log file generated by the application at run time.

`RPMFILE_LICENSE`

The file contains the license conditions.

`RPMFILE_README`

The file contains high level notes about the package.

`RPMFILE_EXCLUDE`

The corresponding file is not a part of the package, and should not be installed.

22.2.4.4 Dependency Information

The following tag values are used to provide information about interdependencies between packages.

Table 22-12 Package Dependency Tag Values

Name	Tag Value	Type	Count	Status
`RPMTAG_PROVIDENAME`	1047	STRING_ARRAY	1	Required
`RPMTAG_REQUIREFLAGS`	1048	INT32		Required
`RPMTAG_REQU`	1049	STRING_AR		Required

Name	Tag Value	Type	Count	Status
IRENAME		RAY		
RPMTAG_REQUIREVERSION	1050	STRING_ARRAY		Required
RPMTAG_CONFLICTFLAGS	1053	INT32		Optional
RPMTAG_CONFLICTNAME	1054	STRING_ARRAY		Optional
RPMTAG_CONFLICTVERSION	1055	STRING_ARRAY		Optional
RPMTAG_OBSOLETENAME	1090	STRING_ARRAY		Optional
RPMTAG_PROVIDEFLAGS	1112	INT32		Required
RPMTAG_PROVIDEVERSION	1113	STRING_ARRAY		Required
RPMTAG_OBSOLETEFLAGS	1114	INT32	1	Optional
RPMTAG_OBSOLETEVERSION	1115	STRING_ARRAY		Optional

RPMTAG_PROVIDENAME

This tag indicates the name of the dependency provided by this package.

RPMTAG_REQUIREFLAGS

Bits(s) to specify the dependency range and context.

RPMTAG_REQUIRENAME

This tag indicates the dependencies for this package.

RPMTAG_REQUIREVERSION

This tag indicates the versions associated with the values found in the RPMTAG_REQUIRENAME Index.

RPMTAG_CONFLICTFLAGS

Bits(s) to specify the conflict range and context.

RPMTAG_CONFLICTNAME

This tag indicates the conflicting dependencies for this package.

RPMTAG_CONFLICTVERSION

This tag indicates the versions associated with the values found in the RPMTAG_CONFLICTNAME Index.

RPMTAG_OBSOLETENAME

This tag indicates the obsoleted dependencies for this package.

RPMTAG_PROVIDEFLAGS

Bits(s) to specify the conflict range and context.

RPMTAG_PROVIDEVERSION

This tag indicates the versions associated with the values found in the RPMTAG_PROVIDENAME Index.

RPMTAG_OBSOLETEFLAGS

Bits(s) to specify the conflict range and context.

RPMTAG_OBSOLETEVERSION

This tag indicates the versions associated with the values found in the RPMTAG_OBSOLETENAME Index.

22.2.4.4.1 Package Dependency Values

The package dependencies are stored in the RPMTAG_REQUIRENAME and RPMTAG_REQUIREVERSION index records. The following values may be used.

Table 22-13 Index Type values

Name	Version	Meaning	Status
rpmlib(VersionedDependencies)	3.0.3-1	Indicates that the package contains RPMTAG_PROVIDENAME, RPMTAG_OBSOLETENAME or RPMTAG_PREREQ records that have a version associated with them.	Optional
rpmlib(PayloadFilesHavePrefix)	4.0-1	Indicates the filenames in the Archive have had "." prepended to them.	Optional
rpmlib(CompressedFileNames)	3.0.4-1	Indicates that the filenames in the Payload are represented in the RPMTAG_DIRINDEXES, RPMTAG_DIRNAME and RPMTAG_BASENAMES indexes.	Optional
/bin/sh		Interpreter usually required for installation scripts.	Optional

Additional dependencies are specified in the Package Dependencies section of this ~~document~~specification, and the architecture specific ~~documents~~supplements.

22.2.4.4.2 Package Dependencies Attributes

The package dependency attributes are stored in the `RPMTAG_REQUIREFLAGS`, `RPMTAG_PROVIDEFLAGS` and `RPMTAG_OBSOLETEFLAGS` index records. The following values may be used.

Table 22-14 Package Dependency Attributes

Name	Value	Meaning
`RPMSENSE_LESS`	`0x02`	
`RPMSENSE_GREATER`	`0x04`	
`RPMSENSE_EQUAL`	`0x08`	
`RPMSENSE_PREREQ`	`0x40`	
`RPMSENSE_INTERP`	`0x100`	
`RPMSENSE_SCRIPT_PRE`	`0x200`	
`RPMSENSE_SCRIPT_POST`	`0x400`	
`RPMSENSE_SCRIPT_PREUN`	`0x800`	
`RPMSENSE_SCRIPT_POSTUN`	`0x1000`	
`RPMSENSE_RPMLIB`	`0x1000000`	

22.2.4.5 Other Information

The following tag values are also found in the Header section.

Table 22-15 Other Tag Values

Name	Tag Value	Type	Count	Status
`RPMTAG_BUILDTIME`	1006	INT32	1	Informational
`RPMTAG_BUILDHOST`	1007	STRING	1	Informational
`RPMTAG_FILEVERIFYFLAGS`	1045	INT32		Optional
`RPMTAG_CHANGELOGTIME`	1080	INT32		Optional
`RPMTAG_CHANGELOGNAME`	1081	STRING_ARRAY		Optional
`RPMTAG_CHANGELOGTEXT`	1082	STRING_ARRAY		Optional
`RPMTAG_OPTFLAGS`	1122	STRING	1	Informational
`RPMTAG_RHNP`	1131	STRING	1	Deprecated

Name	Tag Value	Type	Count	Status
LATFORM				
RPMTAG_PLATFORM	1132	STRING	1	Informational

RPMTAG_BUILDTIME

This tag specifies the time as seconds since the epoch at which the package was built.

RPMTAG_BUILDHOST

This tag specifies the hostname of the system on which which the package was built.

RPMTAG_FILEVERIFYFLAGS

This tag specifies the bit(s) to control how files are to be verified after install, specifying which checks should be performed.

RPMTAG_CHANGELOGTIME

This tag specifies the Unix time in seconds since the epoch associated with each entry in the Changelog file.

RPMTAG_CHANGELOGNAME

This tag specifies the name of who made a change to this package

RPMTAG_CHANGELOGTEXT

This tag specifies the changes asssociated with a changelog entry.

RPMTAG_OPTFLAGS

This tag indicates additional flags which may have been passed to the compiler when building this package.

RPMTAG_RHNPLATFORM

This tag contains an opaque string whose contents are undefined.

RPMTAG_PLATFORM

This tag contains an opaque string whose contents are undefined.

22.2.5 Payload Section

The Payload section contains a compressed cpio archive. The format of this section is defined by RFC 1952: GZIP File Format Specification.

When uncompressed, the cpio archive contains a sequence of records for each file. Each record contains a CPIO Header, Filename, Padding, and File Data.

Table 22-16 CPIO File Format

CPIO Header	Header structure as defined below.
Filename	NUL terminated ASCII string containing the name of the file.
Padding	0-3 bytes as needed to align the file

	stream to a 4 byte boundary.
File data	The contents of the file.
Padding	0-3 bytes as needed to align the file stream to a 4 byte boundary.

The CPIO Header uses the following header structure (sometimes referred to as "new ASCII" or "SVR4 cpio"). All numbers are stored as ASCII representations of their hexadecimal value with leading zeros as needed to fill the field. With the exception of *c_namesize* and the corresponding name string, and *c_checksum,* all information contained in the CPIO Header is also represented in the Header Section. The values in the CPIO Header shall match the values contained in the Header Section.

```
struct {
        char    c_magic[6];
        char    c_ino[8];
        char    c_mode[8];
        char    c_uid[8];
        char    c_gid[8];
        char    c_nlink[8];
        char    c_mtime[8];
        char    c_filesize[8];
        char    c_devmajor[8];
        char    c_devminor[8];
        char    c_rdevmajor[8];
        char    c_rdevminor[8];
        char    c_namesize[8];
        char    c_checksum[8];
        };
```

c_magic

Value identifying this cpio format. This value shall be "070701".

c_ino

This field contains the inode number from the filesystem from which the file was read. This field is ignored when installing a package. This field shall match the corresponding value in the `RPMTAG_FILEINODES` index in the Header section.

c_mode

Permission bits of the file. This is an ascii representation of the hexadecimal number representing the bit as defined for the *st_mode* field of the `stat` structure defined for the `stat` function. This field shall match the corresponding value in the `RPMTAG_FILEMODES` index in the Header section.

c_uid

Value identifying this owner of this file. This value matches the uid value of the corresponding user in the RPMTAG_FILEUSERNAME as found on the system where this package was built. The username specified in RPMTAG_FILEUSERNAME should take precedence when installing the package.

499 *c_gid*

500 Value identifying this group of this file. This value matches the gid value of the
501 corresponding user in the RPMTAG_FILEGROUPNAME as found on the
502 system where this package was built. The groupname specified in
503 RPMTAG_FILEGROUPNAME should take precedence when installing the
504 package.

505 *c_nlink*

506 Value identifying the number of links associated with this file. If the value is
507 greater than 1, then this filename will be linked to 1 or more files in this archive
508 that has a matching value for the c_ino, c_devmajor and c_devminor fields.

509 *c_mtime*

510 Value identifying the modification time of the file when it was read. This field
511 shall match the corresponding value in the `RPMTAG_FILEMTIMES` index in the
512 Header section.

513 *c_filesize*

514 Value identifying the size of the file. This field shall match the corresponding
515 value in the `RPMTAG_FILESIZES` index in the Header section.

516 *c_devmajor*

517 The major number of the device containing the file system from which the file
518 was read. With the exception of processing files with c_nlink >1, this field is
519 ignored when installing a package. This field shall match the corresponding
520 value in the `RPMTAG_FILEDEVICES` index in the Header section.

521 *c_devminor*

522 The minor number of the device containing the file system from which the file
523 was read. With the exception of processing files with c_nlink >1, this field is
524 ignored when installing a package. This field shall match the corresponding
525 value in the `RPMTAG_FILEDEVICES` index in the Header section.

526 *c_rdevmajor*

527 The major number of the raw device containing the file system from which the
528 file was read. This field is ignored when installing a package. This field shall
529 match the corresponding value in the `RPMTAG_RDEVS` index in the Header
530 section.

531 *c_rdevminor*

532 The minor number of the raw device containing the file system from which the
533 file was read. This field is ignored when installing a package. This field shall
534 match the corresponding value in the `RPMTAG_RDEVS` index in the Header
535 section.

536 *c_namesize*

537 Value identifying the length of the filename, which is located immediately
538 following the CPIO Header structure.

`c_checksum`

Value containing the CRC checksum of the file data. This field is not used, and shall contain the value "00000000". This field is ignored when installing a package.

A record with the filename "TRAILER!!!" indicates the last record in the archive.

22.3 Package Script Restrictions

Scripts used as part of the package install and uninstall shall only use commands and interfaces that are specified by the LSB. All other commands are not guaranteed to be present, or to behave in expected ways.

Packages shall not use RPM triggers.

Packages shall not depend on the order in which scripts are executed (pre-install, pre-uninstall, etc), when doing an upgrade.

22.4 Package Tools

The LSB does not specify the interface to the tools used to manipulate LSB-conformant packages. Each conforming ~~distribution~~implementation shall provide documentation for installing LSB packages.

22.5 Package Naming

Packages supplied by ~~distributions~~implementations and applications ~~must~~ shall follow the following rules for the name field within the package. These rules are not required for the filename of the package file itself.[1]

~~1 For example, there~~**Note:** There are discrepancies among ~~distributions~~implementations concerning whether the name might be `frobnicator-1.7-21-ppc32.rpm` or `frobnicator-1.7-21-powerpc32.rpm`. The architecture aside, recommended practice is for the filename of the package file to match the name within the package.

The following rules apply to the name field alone, not including any release or version.[2]

~~2 For example, if~~**Note:** If the name with the release and version is `frobnicator-1.7-21`, the name part is `frobnicator` and falls under the rules for a name with no hyphens.

- If the name begins with "`lsb-`" and contains no other hyphens, the name shall be assigned by the Linux Assigned Names and Numbers Authority (http://www.lanana.org) (LANANA), which shall maintain a registry of LSB names. The name may be registered by either ~~a distribution~~an implementation or an application.
- If the package name begins with "`lsb-`" and contains more than one hyphen (for example "`lsb-distro.example.com-database`" or "`lsb-gnome-gnumeric`"), then the portion of the package name between first and second hyphens shall either be an LSB provider name assigned by the LANANA, or it may be one of the owners' fully-qualified domain names in lower case (e.g., "`debian.org`", "`staroffice.sun.com`"). The LSB provider name assigned by LANANA shall only consist of the ASCII characters [a-z0-9]. The provider name or domain name may be either that of ~~a distribution~~an implementation or an application.

- Package names containing no hyphens are reserved for use by ~~distributions~~implementations. Applications ~~must~~shall not use names.[3]

~~3 For example, "frobnicator".~~

- Package names which do not start with "`lsb-`" and which contain a hyphen are open to both ~~distributions~~implementations and applications. ~~Distributions~~Implementations may name packages in any part of this namespace. They are encouraged to use names from one of the other namespaces available to them, but this is not required due to the large amount of current practice to the contrary.[4]

  ~~4 For example,~~ **Note:** Widespread existing practice includes such names as `ssh-common`, `ssh-client`, `kernel-pcmcia`, and the like. Possible alternative names include `sshcommon`, `foolinux-ssh-common` (where `foolinux` is registered to the ~~distribution~~implementation), or `lsb-foolinux-ssh-common`.

  Applications may name their packages this way, but only if the portion of the name before the first hyphen is a provider name or registered domain name as described above.[5]

  ~~5 For example, if~~**Note:** If an application vendor has domain name such as `visicalc.example.com` and has registered `visicalc` as a provider name, they might name packages `visicalc-base`, `visicalc.example.com-charting`, and the like.

  ~~Note that package~~Package names in this namespace are available to both the ~~distribution~~implementation and an application. ~~Distributions~~Implementations and applications will need to consider this potential for conflicts when deciding to use these names rather than the alternatives (such as names starting with "`lsb~~")~~.-~~)~~.

22.6 Package Dependencies

Packages shall have a dependency that indicates which LSB modules are required. LSB module descriptions are dash seperated tuples containing the name 'lsb', the module name, and the architecture name. The following dependencies may be used.

lsb-core-*arch*

This dependency is used to indicate that the application is dependent on features contained in the LSB-Core specification.

lsb-core-noarch

This dependency is used to indicate that the application is dependent on features contained in the LSB-Core specification and that the package does not contain any architecture specific files.

These dependencies shall have a version of 3.0.

Packages shall not depend on other system-provided dependencies. They shall not depend on non-system-provided dependencies unless those dependencies are fulfilled by packages which are part of the same application. A package may only provide a virtual package name which is registered to that application.

Other modules in the LSB may supplement this list. The architecture specific dependencies are described in the relevant architecture specific LSB.

22.7 Package Architecture Considerations

Packages which do not contain any architecture specific files ~~must~~should specify an architecture of `noarch`. An LSB runtime environment ~~must~~shall accept values `noarch`, or the value specified in the architecture specific supplement.

Additional specifications or restrictions may be found in the architecture specific LSB specification.

Annex A Alphabetical Listing of Interfaces

A.1 libc

The behavior of the interfaces in this library is specified by the following Standards.

Large File Support [LFS]
~~this specification~~This Specification [LSB]
SUSv2 [SUSv2]
ISO POSIX (2003) [SUSv3]
SVID Issue 3 [SVID.3]
SVID Issue 4 [SVID.4]

Annex B Future Directions (Informative)

B.1 Introduction

This appendix describes interfaces that are under development and aimed at future releases of this specification. At this stage, such interfaces are at best recommended practice, and do not constitute normative requirements of this specification. Applications may not assume that any system provides these interfaces.

We encourage system implementors and ISVs to provide these interfaces, and to provide feedback on their specification to lsbspec@freestandards.org (mailto://lsb-spec@freestandards.org). These interfaces may well be further modified during the development process, and may be withdrawn if concensus cannot be reached.

B.2 Commands And Utilities

lsbinstall

Name

`lsbinstall` — installation tool for various types of data

Synopsis

```
/usr/lib/lsb/lsbinstall [-c | --check | -r | --remove] { -t type | --type=type }
[-p package | --package=package] operand...
```

Description

The **lsbinstall** utility may be used to install certain types of files into system specific locations, repositories, or databases. This command may be used during a package post installation script to add package specific data to system wide repositories. A user may need appropriate privilege to invoke **lsbinstall**.

The operand (or operands) name an object of type *type* (see below) that belongs to a package named *package*. The combination of package name, object type and object name should be unique amongst all objects installed by **lsbinstall**. The **lsbinstall** utility may rename an object if another package already owns an object of the same type with the same name.

> **Note:** If a namespace collision is detected by **lsbinstall**, it is unspecified how the object is renamed, although typical implementations may prepend the package name to the object in some way (e.g. `package.obj-name`). The **lsbinstall** utility may maintain a database of the mappings it has performed during installation in order to ensure that the correct object is removed during a subsequent removal operation.

Scripts installed by **lsbinstall** should not make use of the script name in order to decide on their functionality.

> **Note:** It is appropriate for such a script to use the script name in error messages, usage statements, etc. The only guarantee made by **lsbinstall** is the effect that an installation (or removal) should have, not where a script is installed, or how it is named.

The *-p pkg* or *--package=pkg* is required for all object types unless explicitly noted below.

If the *-c* or *--check* option is specified, **lsbinstall** should test to see if there is an existing object of the type specified already installed. If there is, **lsbinstall** should print a message to its standard output and immediately exit with a status of zero. If there is no object of the type and name specified already installed, **lsbinstall** should exit with a non-zero status and take no further action.

If the *-r* or *--remove* is specified, the named object of the specified type should be removed or disabled from the system, except as noted below. The behavior is unspecified if the named object was not previously installed by **lsbinstall**.

> **Note:** **lsbinstall** may rename objects during installation in order to prevent name collisions where another package has already installed an object with the given name. Using **lsbinstall --remove** will remove only the object belonging to the named package, and not the object belonging to another package.

Also note that the intent of the *--remove* option is to prevent the effect of the installed object; it should be sufficient to disable or comment out the addition in some way, while leaving the content behind. It is not intended that *--remove* be required to be the exact reverse of installation.

Object Types

The *-t type* or *--type=type* option should support at least the following types:

profile

install a profile script into a system specific location. There should be one operand, that names a profile shell script. The behavior is unspecified if this name does not have the suffix `.sh`.

The **sh** utility should read and execute commands in its current execution environment from all such installed profile shell scripts when invoked as an interactive login shell, or if the *-l* (the letter *ell*) is specified (see Shell Invocation).

service

ensure a service name and number pair is known to the system service database. When installing, there must be at least two operands. The first operand should have the format `%d/%s` with the port number and protocol values (e.g. `22/tcp`), and the second operand should be the name of the service. Any subsequent operands provide aliases for this service. The *-p pkg* or *--package=pkg* option is not required for service objects, and is ignored if specified. If any of the *-r*, *--remove*, *-c* or *--check* options are specified, there should be a single operand identifying the port and protocol values (with the same format as above).

It should not be an error to attempt to add a service name to the system service database if that service name already exists for the same port and protocol combination. If the port and protocol combination was already present, but the name unknown, the name should be added as an alias to the existing entry. It should be an error to attempt to add a second entry for a given service name and protocol, but where the port number differs from an existing entry.

If the *-r* or *--remove* is specified, the system service database need not be updated to remove or disable the named service.

inet

add an entry to the system's network super daemon configuration. If none of the *-r*, *--remove*, *-c* or *--check* options are specified, the first operand should have the format:

`"%s:%s:%s:%s:%s:%s"`

Otherwise, the first operand should have the format

`"%s:%s"`

The fields in the first operand have the following meaning, in order:

`svc_name`

The name of this service. If the name does not contain a `/`, this should match the name of an already installed `service` (see also `getservbyname()`). If the name contains a `/` character, the behavior is unspecified.

Rationale: This version of the LSB does not specify `getrpcbyname()` nor the existence or format of the `/etc/rpc` file. Therefore, installation of RPC based services is not specified at this point. A future version of this specification may require names containing a `/` character to be Remote Procedure Call based services.

`protocol`

The name of a protocol. The name should be one of those listed in `/etc/protocols`. If this attribute is not specified (i.e. a null value is passed), the system should use an implementation defined default protocol.

`socket_type`

One of the following values:

`stream`

the service will use a stream type socket.

`dgram`

the service will use a datagram type socket.

`seqpacket`

the service will use a sequenced packet type socket.

This field is not required for the *`-c`*, *`--check`*, *`-r`*, or *`--remove`* options.

`wait_flag`

If the value of this attribute is `wait`, once the service is started, no further requests for that service will be handled until the service exits. If the value is `nowait`, the network super daemon should continue to handle further requests for the given service while that service is running.

Note: If the service has the `socket_type` attribute set to `dgram`, the `wait_flag` attribute should be set to `wait`, since such services do not have any distinction between the socket used for listening and that used for accepting.

This field is not required for the *`-c`*, *`--check`*, *`-r`*, or *`--remove`* options.

`user[.group]`

The name of a user from the user login database, optionally followed by the name of a group from the group database. The service started to handle this request should run with the privileges of the specified user and group. This field is not required for the *`-c`*, *`--check`*, *`-r`*, or *`--remove`* options.

`server [arg ...]`

The name of a program to run to handle the request, optionally followed by any arguments required. The server name and each of its arguments is separated by whitespace. This field is not required for the *`-c`*, *`--check`*, *`-r`*, or *`--remove`* options.

If the implementation supports additional controls over services started through the inet super daemon, there may be additional, implementation-defined, operands.

Rationale: Systems that use the **xinetd** super daemon may support additional controls such as IP address restrictions, logging requirements, etc. The LSB does not require these additional controls. However, it was believed to be of sufficient benefit that implementations are granted permission to extend this interface as required.

Examples

```
lsbinstall --package=myapp --type=profile myco.com-prod.sh
```

Install the profile shell script for `myco.com-prod.sh`, part of the `myapp` package..

```
lsbinstall --package=myapp --check --type=profile myco.com-prod.sh
```

Test to see if the profile shell script for `myco.com-prod.sh`, as part of the `myapp` package, is installed correctly.

Exit Status

If the *`-c`* or *`--check`* option is specified, **lsbinstall** should exit with a zero status if an object of the specified type and name is already installed, or non-zero otherwise. Otherwise, **lsbinstall** should exit with a zero status if the object with the specified type and name was successfully installed (or removed if the *`-r`* or *`--remove`* option was specified), and non-zero if the installation (or removal) failed. On failure, a diagnostic message should be printed to the standard error file descriptor.

Annex C GNU Free Documentation License (Informative)

This specification is published under the terms of the GNU Free Documentation License, Version 1.1, March 2000

Copyright (C) 2000 Free Software Foundation, Inc. 59 Temple Place, Suite 330, Boston, MA 02111-1307 USA Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

C.1 PREAMBLE

The purpose of this License is to make a manual, textbook, or other written document "free" in the sense of freedom: to assure everyone the effective freedom to copy and redistribute it, with or without modifying it, either commercially or noncommercially. Secondarily, this License preserves for the author and publisher a way to get credit for their work, while not being considered responsible for modifications made by others.

This License is a kind of "copyleft", which means that derivative works of the document must themselves be free in the same sense. It complements the GNU General Public License, which is a copyleft license designed for free software.

We have designed this License in order to use it for manuals for free software, because free software needs free documentation: a free program should come with manuals providing the same freedoms that the software does. But this License is not limited to software manuals; it can be used for any textual work, regardless of subject matter or whether it is published as a printed book. We recommend this License principally for works whose purpose is instruction or reference.

C.2 APPLICABILITY AND DEFINITIONS

This License applies to any manual or other work that contains a notice placed by the copyright holder saying it can be distributed under the terms of this License. The "Document", below, refers to any such manual or work. Any member of the public is a licensee, and is addressed as "you".

A "Modified Version" of the Document means any work containing the Document or a portion of it, either copied verbatim, or with modifications and/or translated into another language.

A "Secondary Section" is a named appendix or a front-matter section of the Document that deals exclusively with the relationship of the publishers or authors of the Document to the Document's overall subject (or to related matters) and contains nothing that could fall directly within that overall subject. (For example, if the Document is in part a textbook of mathematics, a Secondary Section may not explain any mathematics.) The relationship could be a matter of historical connection with the subject or with related matters, or of legal, commercial, philosophical, ethical or political position regarding them.

The "Invariant Sections" are certain Secondary Sections whose titles are designated, as being those of Invariant Sections, in the notice that says that the Document is released under this License.

The "Cover Texts" are certain short passages of text that are listed, as Front-Cover Texts or Back-Cover Texts, in the notice that says that the Document is released under this License.

A "Transparent" copy of the Document means a machine-readable copy, represented in a format whose specification is available to the general public, whose contents can be viewed and edited directly and straightforwardly with generic text editors or (for images composed of pixels) generic paint programs or (for drawings) some widely available drawing editor, and that is suitable for input to text formatters or for automatic translation to a variety of formats suitable for input to text formatters. A copy made in an otherwise Transparent file format whose markup has been designed to thwart or discourage subsequent modification by readers is not Transparent. A copy that is not "Transparent" is called "Opaque".

Examples of suitable formats for Transparent copies include plain ASCII without markup, Texinfo input format, LaTeX input format, SGML or XML using a publicly available DTD, and standard-conforming simple HTML designed for human modification. Opaque formats include PostScript, PDF, proprietary formats that can be read and edited only by proprietary word processors, SGML or XML for which the DTD and/or processing tools are not generally available, and the machine-generated HTML produced by some word processors for output purposes only.

The "Title Page" means, for a printed book, the title page itself, plus such following pages as are needed to hold, legibly, the material this License requires to appear in the title page. For works in formats which do not have any title page as such, "Title Page" means the text near the most prominent appearance of the work's title, preceding the beginning of the body of the text.

C.3 VERBATIM COPYING

You may copy and distribute the Document in any medium, either commercially or noncommercially, provided that this License, the copyright notices, and the license notice saying this License applies to the Document are reproduced in all copies, and that you add no other conditions whatsoever to those of this License. You may not use technical measures to obstruct or control the reading or further copying of the copies you make or distribute. However, you may accept compensation in exchange for copies. If you distribute a large enough number of copies you must also follow the conditions in section 3.

You may also lend copies, under the same conditions stated above, and you may publicly display copies.

C.4 COPYING IN QUANTITY

If you publish printed copies of the Document numbering more than 100, and the Document's license notice requires Cover Texts, you must enclose the copies in covers that carry, clearly and legibly, all these Cover Texts: Front-Cover Texts on the front cover, and Back-Cover Texts on the back cover. Both covers must also clearly and legibly identify you as the publisher of these copies. The front cover must present the full title with all words of the title equally prominent and visible. You may add other material on the covers in addition. Copying with changes limited to the covers, as long as they preserve the title of the Document and satisfy these conditions, can be treated as verbatim copying in other respects.

If the required texts for either cover are too voluminous to fit legibly, you should put the first ones listed (as many as fit reasonably) on the actual cover, and continue the rest onto adjacent pages.

If you publish or distribute Opaque copies of the Document numbering more than 100, you must either include a machine-readable Transparent copy along with each

Opaque copy, or state in or with each Opaque copy a publicly-accessible computer-network location containing a complete Transparent copy of the Document, free of added material, which the general network-using public has access to download anonymously at no charge using public-standard network protocols. If you use the latter option, you must take reasonably prudent steps, when you begin distribution of Opaque copies in quantity, to ensure that this Transparent copy will remain thus accessible at the stated location until at least one year after the last time you distribute an Opaque copy (directly or through your agents or retailers) of that edition to the public.

It is requested, but not required, that you contact the authors of the Document well before redistributing any large number of copies, to give them a chance to provide you with an updated version of the Document.

C.5 MODIFICATIONS

You may copy and distribute a Modified Version of the Document under the conditions of sections 2 and 3 above, provided that you release the Modified Version under precisely this License, with the Modified Version filling the role of the Document, thus licensing distribution and modification of the Modified Version to whoever possesses a copy of it. In addition, you must do these things in the Modified Version:

A. Use in the Title Page (and on the covers, if any) a title distinct from that of the Document, and from those of previous versions (which should, if there were any, be listed in the History section of the Document). You may use the same title as a previous version if the original publisher of that version gives permission.

B. List on the Title Page, as authors, one or more persons or entities responsible for authorship of the modifications in the Modified Version, together with at least five of the principal authors of the Document (all of its principal authors, if it has less than five).

C. State on the Title page the name of the publisher of the Modified Version, as the publisher.

D. Preserve all the copyright notices of the Document.

E. Add an appropriate copyright notice for your modifications adjacent to the other copyright notices.

F. Include, immediately after the copyright notices, a license notice giving the public permission to use the Modified Version under the terms of this License, in the form shown in the Addendum below.

G. Preserve in that license notice the full lists of Invariant Sections and required Cover Texts given in the Document's license notice.

H. Include an unaltered copy of this License.

I. Preserve the section entitled "History", and its title, and add to it an item stating at least the title, year, new authors, and publisher of the Modified Version as given on the Title Page. If there is no section entitled "History" in the Document, create one stating the title, year, authors, and publisher of the Document as given on its Title Page, then add an item describing the Modified Version as stated in the previous sentence.

J. Preserve the network location, if any, given in the Document for public access to a Transparent copy of the Document, and likewise the network locations

given in the Document for previous versions it was based on. These may be placed in the "History" section. You may omit a network location for a work that was published at least four years before the Document itself, or if the original publisher of the version it refers to gives permission.

K. In any section entitled "Acknowledgements" or "Dedications", preserve the section's title, and preserve in the section all the substance and tone of each of the contributor acknowledgements and/or dedications given therein.

L. Preserve all the Invariant Sections of the Document, unaltered in their text and in their titles. Section numbers or the equivalent are not considered part of the section titles.

M. Delete any section entitled "Endorsements". Such a section may not be included in the Modified Version.

N. Do not retitle any existing section as "Endorsements" or to conflict in title with any Invariant Section.

If the Modified Version includes new front-matter sections or appendices that qualify as Secondary Sections and contain no material copied from the Document, you may at your option designate some or all of these sections as invariant. To do this, add their titles to the list of Invariant Sections in the Modified Version's license notice. These titles must be distinct from any other section titles.

You may add a section entitled "Endorsements", provided it contains nothing but endorsements of your Modified Version by various parties--for example, statements of peer review or that the text has been approved by an organization as the authoritative definition of a standard.

You may add a passage of up to five words as a Front-Cover Text, and a passage of up to 25 words as a Back-Cover Text, to the end of the list of Cover Texts in the Modified Version. Only one passage of Front-Cover Text and one of Back-Cover Text may be added by (or through arrangements made by) any one entity. If the Document already includes a cover text for the same cover, previously added by you or by arrangement made by the same entity you are acting on behalf of, you may not add another; but you may replace the old one, on explicit permission from the previous publisher that added the old one.

The author(s) and publisher(s) of the Document do not by this License give permission to use their names for publicity for or to assert or imply endorsement of any Modified Version.

C.6 COMBINING DOCUMENTS

You may combine the Document with other documents released under this License, under the terms defined in section 4 above for modified versions, provided that you include in the combination all of the Invariant Sections of all of the original documents, unmodified, and list them all as Invariant Sections of your combined work in its license notice.

The combined work need only contain one copy of this License, and multiple identical Invariant Sections may be replaced with a single copy. If there are multiple Invariant Sections with the same name but different contents, make the title of each such section unique by adding at the end of it, in parentheses, the name of the original author or publisher of that section if known, or else a unique number. Make the same adjustment to the section titles in the list of Invariant Sections in the license notice of the combined work.

In the combination, you must combine any sections entitled "History" in the various original documents, forming one section entitled "History"; likewise combine any sections entitled "Acknowledgements", and any sections entitled "Dedications". You must delete all sections entitled "Endorsements."

C.7 COLLECTIONS OF DOCUMENTS

You may make a collection consisting of the Document and other documents released under this License, and replace the individual copies of this License in the various documents with a single copy that is included in the collection, provided that you follow the rules of this License for verbatim copying of each of the documents in all other respects.

You may extract a single document from such a collection, and distribute it individually under this License, provided you insert a copy of this License into the extracted document, and follow this License in all other respects regarding verbatim copying of that document.

C.8 AGGREGATION WITH INDEPENDENT WORKS

A compilation of the Document or its derivatives with other separate and independent documents or works, in or on a volume of a storage or distribution medium, does not as a whole count as a Modified Version of the Document, provided no compilation copyright is claimed for the compilation. Such a compilation is called an "aggregate", and this License does not apply to the other self-contained works thus compiled with the Document, on account of their being thus compiled, if they are not themselves derivative works of the Document.

If the Cover Text requirement of section 3 is applicable to these copies of the Document, then if the Document is less than one quarter of the entire aggregate, the Document's Cover Texts may be placed on covers that surround only the Document within the aggregate. Otherwise they must appear on covers around the whole aggregate.

C.9 TRANSLATION

Translation is considered a kind of modification, so you may distribute translations of the Document under the terms of section 4. Replacing Invariant Sections with translations requires special permission from their copyright holders, but you may include translations of some or all Invariant Sections in addition to the original versions of these Invariant Sections. You may include a translation of this License provided that you also include the original English version of this License. In case of a disagreement between the translation and the original English version of this License, the original English version will prevail.

C.10 TERMINATION

You may not copy, modify, sublicense, or distribute the Document except as expressly provided for under this License. Any other attempt to copy, modify, sublicense or distribute the Document is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

C.11 FUTURE REVISIONS OF THIS LICENSE

The Free Software Foundation may publish new, revised versions of the GNU Free Documentation License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns. See http://www.gnu.org/copyleft/.

Each version of the License is given a distinguishing version number. If the Document specifies that a particular numbered version of this License "or any later version" applies to it, you have the option of following the terms and conditions either of that specified version or of any later version that has been published (not as a draft) by the Free Software Foundation. If the Document does not specify a version number of this License, you may choose any version ever published (not as a draft) by the Free Software Foundation.

C.12 How to use this License for your documents

To use this License in a document you have written, include a copy of the License in the document and put the following copyright and license notices just after the title page:

> Copyright (c) YEAR YOUR NAME. Permission is granted to copy, distribute and/or modify this document under the terms of the GNU Free Documentation License, Version 1.1 or any later version published by the Free Software Foundation; with the Invariant Sections being LIST THEIR TITLES, with the Front-Cover Texts being LIST, and with the Back-Cover Texts being LIST. A copy of the license is included in the section entitled "GNU Free Documentation License".

If you have no Invariant Sections, write "with no Invariant Sections" instead of saying which ones are invariant. If you have no Front-Cover Texts, write "no Front-Cover Texts" instead of "Front-Cover Texts being LIST"; likewise for Back-Cover Texts.

If your document contains nontrivial examples of program code, we recommend releasing these examples in parallel under your choice of free software license, such as the GNU General Public License, to permit their use in free software.
